The heat of sublimation of iodine was calculated from published vapor pressure data as follows, using thermodynamic functions of condensed and gaseous phases described above.

	$\Delta H_{f, 298}^{\circ}$, kcal. mole ⁻¹
Baxter, Hickey, and Holmes ¹ (273° to 328°K)	15.657 ± .004
Baxter and Grose ² (323° to 358°K)	15.657 ± .002
Ramsay and Young ³ (solid) (331° to 386°K)	15.671 ± .018
Ramsay and Young ³ (liquid) (386° to 454°K)	15.676 ± .007
Haber and Kerschbaum ⁴ (225° to 283°K)	15.765 ± .012
Gillespie and Fraser ⁵ (303° to 333°K)	15.655 ± .005
Sklyarenko, Markin, and Belyaeva ⁶ (283° to 303°K)	15.813
Naumann ⁷ (as given by Haber and Kerschbaum) (232° to 292°K)	15.699 ± .034
Wiedemann ⁸ (333° to 453°K)	15.635 ± .008
Braune and Strassman ⁹ (305° to 358°K)	15.658 ± .012
Arctowski ¹⁰ (286° to 345°K)	15.623 ± .080
Wright ¹¹ (352° to 372°K)	15.659 ± .003
Dewar ¹² (273° to 303°K)	15.821 ± .103
Richter ¹³ (358° to 383°K)	15.639 ± .043

The uncertainties given are the average deviation from the mean. The data of Braune and Strassman are as recalculated by Gerry and Gillespie¹⁴. The data of Haber and Kerschbaum appear systematically too high. The results of Sklyarenko, et al., Naumann, Arctowski, Dewar, and Richter are scattered and are not given any weight. A weighted average of the remaining data yield $\Delta H_{f, 298}^{\circ} = 15.66 \pm 0.01$ kcal. mole⁻¹, which calculates to $\Delta H_{f, 298}^{\circ} = 14.924$ cal. mole⁻¹.

Bond Distance: K-I = [3.29] Å

Bond Angles: K-I-K = [75°] I-K-I = [105°]

Product of the Moments of Inertia: $I_A I_B I_C = [5.041 \times 10^{-11}] \text{ g cm}^6$

$\sigma = [4]$

Heat of Formation

The chemical equilibrium for the reaction $K_2I_2(g) = 2KI(g)$ has been studied by S. Datz, ORNL-2933, Oak Ridge, Tenn., 1960, and S. Datz, W. T. Smith, Jr. and E. H. Taylor, J. Chem. Phys. 34, 588 (1961). They measured the temperature dependence of the molecular weight of $KI(g)$ which was determined by measurement of the absolute pressure exerted by a known weight of completely vaporized salt contained in an isothermal fused silica bulb of known volume. Based on the reported P-V-T measurements, the enthalpy change of the reaction at 298°K is evaluated by the second and third law methods. The results are given in the table below.

R. C. Miller and P. Kusch, J. Chem. Phys. 25, 860 (1956), determined the molecular composition of KI vapor by measurement of the velocity distribution of the molecules in the beam produced as the vapor effused through a small slit in a source. The analysis was based on an assumption that the velocity distribution within the oven is Maxwellian and that the vapor effuses through the ideal slit of kinetic theory. The velocity distributions of potassium and thallium atomic beams were found to be in excellent agreement with the theoretical distributions, so the determination of the molecular composition of KI beams was tried. Using the derived equilibrium constants, we calculate the enthalpy change of the dissociation reaction by the second and third law methods. The results are presented in the following table.

The value of $\Delta H_{298}^\circ(K_2I_2, g)$ is adopted as $-100.9 \pm 1 \text{ kcal/mol}$.

Investigator	Temperature, °K	No. of Points	$\Delta H_{298}^\circ, \text{kcal/mol}$	Drift, au	$\Delta H_{298}^\circ, \text{kcal/mol}$

Heat Capacity

The molecular structure and bond distance and angles were estimated by J. Berkowitz, J. Chem. Phys. 29, 1386 (1958). The vibrational frequencies are estimated by comparison with those calculated by J. Berkowitz, J. Chem. Phys. 32, 1519 (1960), and adjusted to give good agreement between second and third law evaluations of the equilibrium data. The three principal moments of inertia are: $I_A = 5.194 \times 10^{-38}$, $I_B = 2.866 \times 10^{-37}$, $I_C = 3.366 \times 10^{-37} \text{ g cm}^2$.

σ = 4

Heat of Formation

This was obtained from the heat of formation of the crystal and the heat of sublimation of the dimer, which derivation has been given in the LiI(g) table.

Heat Capacity and Entropy

J. Berkowitz, J. Chem. Phys. 29, 1366 (1958), 32, 1519 (1960), has calculated the molecular structure and vibrational frequencies based on an ionic model. The planar rhombic structure, proposed by Berkowitz, has been confirmed by the lack of polarity in electric deflection by A. Büchler, J. L. Stauffer and W. Klemperer, J. Am. Chem. Soc. 86, 4544 (1964). The selected bond distances and angle were obtained from the electron diffraction studies of monomer-dimer vapor by P. A. Akishin and N. G. Rambidi, Z. Physik Chem. 213, 111 (1960). The bond distances (r_{Li-I} = 2.72 Å and r_{I-I} = 4.520 Å) calculated by Berkowitz are in good agreement with those from Akishin and Rambidi. The three principal moments of inertia are I_A = 4.2152 X 10⁻³⁹, I_B = 194.8074 X 10⁻³⁹ and I_C = 199.0226 X 10⁻³⁹ g cm².

S. H. Bauer, T. Ito and R. F. Porter, J. Chem. Phys. 33, 685 (1960), have estimated six vibrational frequencies (501, 501, 148, 200, 298, 360 cm⁻¹) for Li₂I₂(g) in the electron diffraction studies of the Li₂Cl₂(g). W. Klemperer and M. O. Norris, J. Chem. Phys. 35, 1071 (1961), have observed two fundamental vibrational frequencies (248 and 375 cm⁻¹) in the infrared spectrum and tentatively assigned them as B_{2u} and B_{3u} modes; these have been adopted in the tabulation. The remaining four vibrational frequencies were obtained from J. Berkowitz, loc. cit., because his model and derivation are self-consistent.

Lead Diiodide (PbI₂)

(crystal)

Mol. Wt. = 461.03

ΔH°_f 298.15 = -41.86 ± 0.06 kcal. mole⁻¹S°_{298.15} = 41.869 cal. deg.⁻¹ mole⁻¹ΔH°_f 298.15 = 41.70 ± 0.10 kcal. mole⁻¹T_m = 680°K.ΔH°_m = 3.87 kcal. mole⁻¹

Heat of Formation. Calculated from the data reported by H. Braune and F. Kref, Z. anorg. Chem. 87, 175 (1914) and R. H. Gerike, J. Am. Chem. Soc. 44, 1684 (1922).

Heat Capacity, Entropy, and Melting Data. C_p (10° to 298.15°K.) obtained from Edgar F. Westrum, Jr., University of Michigan, Ann Arbor, Michigan, private communication, May, 1961. Above 298.15°K., C_p given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation. T_m and ΔH°_m reported by M. Blanc and G. Petit, Compt. rend., 248, 1305 (1959).

Heat of Sublimation. Calculated from vapor pressure data of K. Jellinek and A. Rudat, Z. Physik. Chem., A143, 55 (1929) and B. Ordiner and K. Jellinek, Z. Physik. Chem., A165, 97 (1933).

Lead Diiodide (PbI₂) (Liquid)

Mol. Wt. = 461.03

 $\Delta H_f^\circ 298.15 = [-40.657] \text{ kcal. mole}^{-1}$ $S_{298.15}^\circ = [42.786] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $T_m = 680^\circ \text{K.}$ $\Delta H_m^\circ = 3.67 \text{ kcal. mole}^{-1}$ $T_b = 1135^\circ \text{K.}$ $\Delta H_v^\circ = 26.99 \pm 0.10 \text{ kcal. mole}^{-1}$

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p obtained from K.K. Kelley, U. S. Bur. Mines Bull. 584 (1950). T_m and ΔH_m° re-

ported by M. Blanc and G. Petit, Compt. rend. 248, 1305-6 (1959).

A glass transition temperature of 454°K. is assumed.Vaporization Phenomena. T_b and ΔH_v° calculated from $\Delta H_f^\circ 298.15$

and free energy functions for condensed and gaseous states.

Lead Diiodide (PbI₂) (Ideal Gas)

Mol. Wt. = 461.03
 ΔH_f^0 298.15 = -0.16 ± 0.12 kcal. mole⁻¹
 $S_{298.15}^0$ = [85.911] cal. deg.⁻¹ mole⁻¹
 Point group C_{2v}

Vibrational Levels and Multiplicities

ω, cm. ⁻¹
[100] (1)
[40] (1)
[160] (1)

Pb-I distance = 2.79 ± 0.02 Å IPBI angle = 85° σ = 2
 I_A = 67.294 X 10⁻³⁹ g. cm.² I_B = 178.298 X 10⁻³⁹ g. cm.²
 I_C = I_A + I_B = 245.592 X 10⁻³⁹

Heat of Formation. Calculated from ΔH_f^0 298.15 and ΔH_f^0 298.15 for PbI₂(c).

Heat Capacity and Entropy. Molecular dimensions obtained from L. E. Sutton (ed.), "Tables of Interatomic Distances and Configuration in Molecules and Ions," The Chemical Society, London, 1958. Vibrational frequencies estimated by comparison with the corresponding values for HgI₂(E).

TITANIUM DIODIDE (TiI₂) (CRYSTAL)

GFW = 301.7088

Titanium Diiodide (TiI₂)

GFW = 301.7088

 $\Delta H_f^\circ = \text{unknown}$ $\Delta H_f^\circ_{298.15} = -63.6 \pm 3.0 \text{ kcal/mol}$ $\Delta H_s^\circ = [51.80] \text{ kcal/mol}$ $S^\circ_{298.15} = [29.3 \pm 3.0] \text{ gibbs/mol}$ $T_m = [1358.2]^\circ\text{K}$

Heat of Formation

The heat of formation of TiI₂(c) is calculated from the heat of reaction for the process $2\text{TiI}_2(\text{c}) = \text{Ti}(\text{c}) + \text{TiI}_4(\text{g})$, and the heat of formation of TiI₄(c). Vapor pressure data for this reaction were reported by Herczog and Pidgeon (1) over the temperature range 750° to 902°K. Second and third law analyses of these data give values for ΔH°_{298} of 60.5 ± 0.8 and 60.85 kcal/mol respectively, the third law drift being $0.4 \pm 1.0 \text{ au}$. The third law ΔH°_{298} is used to obtain the adopted value of ΔH°_{298} .

Heat Capacity and Entropy

The estimated heat capacity is that reported by Kelley (2). The value of $S^\circ_{298.15}$ is estimated from that of TiCl₂(c) and the difference between ionic entropy contributions of Cl⁻ and I⁻.

Heat of Sublimation

The heat of sublimation of TiI₂(c) is taken as the difference in the heats of formation of TiI₂(c) and TiI₂(g) at the sublimation temperature. The sublimation temperature is taken as the point at which $\Delta G_s^\circ = 0$ for the reaction $\text{TiI}_2(\text{c}) = \text{TiI}_2(\text{g})$.

Rotational Constant: $B_0 = [0.0081] \text{ cm}^{-1}$ $\sigma = 2$

Heat of Formation

The heat of formation of $\text{TiI}_2(\text{g})$ is calculated from that of $\text{TiI}_2(\text{c})$ and the heat of vaporization. Vapor pressure data over the temperature range 750°K to 902°K have been reported by Herzog and Pidgeon (1). Second and third law analyses of these data give values for ΔH_{298}° of 51.9 and 58.9 kcal/mol, respectively. The third law drift for these data is 8.3 ± 1.1 eu, with one point rejected due to failure of a statistical test. The adopted value of ΔH_{298}° is calculated from the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of $\text{TiCl}_2(\text{g})$, $\text{TiCl}_4(\text{g})$, $\text{TiBr}_2(\text{g})$, $\text{TiBr}_4(\text{g})$ and $\text{TiI}_4(\text{g})$. The vibrational frequencies are estimated from a valence force field model. The force constant K is estimated as 1.0 millidynes/Å and the constant K_0/l^2 is assumed to be 0.05 millidynes/Å.

The electronic levels are assumed to be the same as $\text{TiCl}_2(\text{g})$. The levels of TiCl_2 are estimated by assuming they correspond to the inverted states of $\text{NiCl}_2(\text{g})$ (2). The linear configuration is adopted, since experimental evidence indicates that other transition metal dihalides are linear (3, 4, 5, 6).

Zirconium Dioxide (ZrI_2) (Crystal)

Mol. Wt. = 345.04

ΔH°_f 298.15 = [-62] kcal. mole⁻¹

$S^\circ_{298.15}$ = [35.8] cal. deg.⁻¹ mole⁻¹

T_m = [700]°K.

ΔH°_m = [6] kcal. mole⁻¹

T_b = [1300]°K.

ΔH°_v = [27] kcal. mole⁻¹

Heat of Formation. Estimated from a consideration of ΔH°_f $ZrI_4(c)$ and of the disproportionation data given by R. F. Rolsten, "Iodide Metals and Metal Iodides", John Wiley and Sons, Inc., New York, (1961).

Heat Capacity and Entropy. Heat capacity estimated by comparison to the other zirconium halides and titanium halides. Entropy estimated from additive constants.

Melting and Vaporization. ΔH°_m was estimated. T_m , T_b , and ΔH°_v from L. Brewer, National Nuclear Energy Series, Div. IV, 196, paper 7, McGraw-Hill Book Co., Inc., New York, 1950.

rZr-I = [2.66 Å]

Δ I-Zr-I = 120°

σ = 2

Product of Moments of Inertia I_AI_BI_C = 1.0716 X 10⁻¹¹¹ g.³ cm.⁶Heat of Formation. Based upon the estimated value of the ΔH_f⁰ for the crystal and the appropriate crystal and gas functions.

Heat Capacity and Entropy. Molecular constants were all estimated by comparison to similar molecules of zirconium and titanium.

TITANIUM TRIIODIDE (TiI₃) (CRYSTAL) GFW = 428.6132

$\Delta H_f^\circ = \text{unknown}$

$\Delta H_{298.15}^\circ = [-77 \pm 5] \text{ kcal/mol}$

$\Delta H_s^\circ = [35.4] \text{ kcal/mol}$

$S_{298.15}^\circ = [46.0 \pm 2.0] \text{ gibbs/mol}$

$T_s = [1000]^\circ\text{K}$

Heat of Formation

The heat of formation of TiI₃(c) is calculated from the free energy of formation at 823°K combined with the increment $\Delta G_{823}^\circ - \Delta G_{298.15}^\circ$ of TiI₂(c), TiI₃(c) and TiI₄(g). The free energy of formation, $\Delta G_{298.15}^\circ$, is estimated such that $\Delta G_{298.15}^\circ = 0$ for the process $2\text{TiI}_3(\text{c}) = \text{TiI}_2(\text{c}) + \text{TiI}_4(\text{g})$. This assumption is based on the observations of Herczog and Pidgeon (1) and Fast (2).

Heat Capacity and Entropy

The heat capacities of TiI₃(c) and the value of $S_{298.15}^\circ$ estimated by Kelley (3) have been adopted.

Heat of Sublimation

The heat of sublimation of TiI₃(c) is taken as the difference in the heats of formation of TiI₃(c) and TiI₃(g) at the sublimation temperature. The sublimation temperature is estimated as the point at which $\Delta G^\circ = 0$ for the process $\text{TiI}_3(\text{c}) = \text{TiI}_3(\text{g})$.

June 30, 1964; Dec. 31, 1968

Bond Distance: Ti-I = [2.7] Å

Bond Angle: I-Ti-I = [100°]

$\sigma = 3$

Product of the Moments of Inertia: $I_{A-B-C} = [1.3 \times 10^{-110}] \text{ g cm}^6$

Heat of Formation

The heat of formation, ΔH_f° , of $\text{TiI}_3(\text{g})$ is estimated from the average Ti-I bond energy. The bond energy is estimated from the corresponding quantities for $\text{TiBn}_3(\text{g})$, $\text{TiBn}_3(\text{g})$, and $\text{TiI}_4(\text{g})$.

Heat Capacity and Entropy

The internuclear distance is estimated from those of TiI_4 , TiCl_4 , and TiCl_3 . The pyramidal bond angle is estimated by assuming that $\text{TiI}_3(\text{g})$ is similar to the group V trihalides. The principal moments of inertia are $I_A = I_B = 1.9 \times 10^{-37} \text{ g cm}^2$ and $I_C = 3.6 \times 10^{-37} \text{ g cm}^2$. The vibrational frequencies are estimated from valence force field predictions and comparisons with group V trihalides. The electronic levels are estimated from the levels of Ti^{+3} reported by C. E. Moore, U. S. Natl. Bur. Std., Circ. 467, 1949.

June 30, 1962; June 30, 1964

ZIRCONIUM TRIIODIDE (ZrI_3) (CRYSTAL) MOL. WT. = 471.950

$S^\circ_{298.15} = [48.90] \text{ cal. mole}^{-1} \text{ deg.}^{-1}$
 $T_g = [970]^\circ\text{K.}$
 $T_d = [1000]^\circ\text{K.}$
 $\Delta H^\circ_f 0 = [-95] \text{ kcal. mole}^{-1}$
 $\Delta H^\circ_f 298.15 = [-95] \text{ kcal. mole}^{-1}$
 $\Delta H^\circ_g 298.15 = [42] \text{ kcal. mole}^{-1}$

Heat of Formation.

E. M. Larson and J. J. Leddy, *J. Am. Chem. Soc.* 78, 5985 (1956), studied the reaction $Zr(c) + 3ZrI_3(g) = 4ZrI_3(c)$ in the temperature range 475 to 975°K. and pressure range 5 to 15 atm. They present a plot of the fractional reaction, at a number of temperatures, as a function of reaction time; however, they express doubt concerning the attainment of thermodynamic equilibrium.

The free energy function change for this reaction was calculated at 100° intervals from 500 to 1100°K. At each temperature the equilibrium constant was assumed to be 1, and ΔH°_{298} accordingly calculated. These values and the heat of formation of $ZrI_4(g)$ [see ZrI_4 table] were used to compute a series of values for the heat of formation of $ZrI_3(c)$ at 298.15°K. The following table gives representative values at four temperatures.

T (°K.)	K_p	ΔH°_{298}	$\Delta H^\circ_{298.15} [ZrI_3(c)]$
500	1	-86.0 kcal. mole ⁻¹	-80.2 kcal. mole ⁻¹
700	1	-80.3 kcal. mole ⁻¹	-86.2 kcal. mole ⁻¹
900	1	-113.5 kcal. mole ⁻¹	-92.1 kcal. mole ⁻¹
1100	1	-135.9 kcal. mole ⁻¹	-97.7 kcal. mole ⁻¹

If one assumes an initial pressure of from 5 to 10 atm. for ZrI_4 and stoichiometric amounts of reactants, then, on the basis of zirconium, the reaction must proceed to the extent of 80 to 90% for the pressure of ZrI_4 to attain a value of 1 atm. and hence an equilibrium constant of 1. The data of Larson and Leddy indicate that the reaction proceeds to the extent of 89% at 975°K. From this it was assumed that at around 1000°K. the equilibrium constant attains a value of 1 giving -95 kcal. mole⁻¹ for the heat of formation of ZrI_3 at 298.15°K.

Their data was subjected to a second law calculation but the results are of doubtful value in view of the uncertainty in the attainment of thermodynamic equilibrium at the lower temperatures. The limits of error assigned to the heat of formation are $\pm 15 \text{ kcal. mole}^{-1}$ corresponding to a temperature spread of $\pm 500^\circ$ in the above table.

Heat Capacity and Entropy.

The heat capacity was estimated in the same manner as for $ZrBr_3(c)$ [see $ZrBr_3(c)$ table]. The values $\theta_D = 60^\circ\text{K.}$ and $\theta_E = 115^\circ\text{K.}$ were taken to be the same as those estimated for $ZrI_4(c)$. The internal contribution was obtained from the estimated ZrI_3 vibrational frequencies and the anharmonicity factor, " a ", was taken to be 2.5×10^{-3} . The specific heat above 300°K. was obtained by graphical extrapolation.

For the above estimation, it was assumed that the crystalline lattice is made up of ZrI_3 molecules. However, E. Holze [see R. F. Rolsten, "Iodide Metals and Metal Iodides", John Wiley & Sons, Inc., New York, 1961, page 46] came to the conclusion that crystalline ZrI_3 is composed of a chain lattice of $(ZrI_3)_n$ units. The results of an analysis for a crystalline lattice composed of Zr_2I_6 units would probably not differ significantly from that for a crystalline lattice composed of ZrI_3 units since both are approaching the classical harmonic heat capacity of 12R calories per formula weight of ZrI_3 at relatively low temperatures.

Until more quantitative information becomes available, it is felt that the above analysis gives a fair approximation to the heat capacity of ZrI_3 .

Temperature of Disproportionation.

As described in the "Heat of Formation" section, this was assumed to be $1000^\circ \pm 500^\circ\text{K.}$

Liquid Phase.

It is assumed that the liquid phase is thermodynamically unstable under ordinary conditions.

Sublimation Data.

The heat of sublimation at 298.15°K. was obtained from the difference in the heats of formation of the gas and solid at 298.15°K. The sublimation point was obtained from the free energy crossover between gas and solid.

Heat of Formation.

The heats of formation, from the gaseous atoms, of the gaseous zirconium tetrahalides were computed from data issued in these tables. The zirconium-halide bond energy, taken as 1/4 of this heat of formation, was found to be linear with internuclear separation. From gaseous titanium tri- and tetrachloride, it was found that the bond energy of the trichloride was around 7 kcal. mole⁻¹ greater than that for titanium tetrachloride. This amount was added to the bond energy of zirconium tetrachloride to get that of zirconium trichloride which, when used with its estimated internuclear distance, was found to lie almost exactly on the bond energy versus internuclear distance curve for the tetrahalides. The bond energy for each of the gaseous trihalides of zirconium was determined from this curve and their estimated bond distances.

For zirconium triiodide, the heat of formation from the gaseous atoms was -275 kcal. mole⁻¹ and from the elements in their standard state, -55 kcal. mole⁻¹.

Heat Capacity and Entropy.

The measured internuclear distances for the triiodides of phosphorus, arsenic, and antimony were plotted as a function of the atomic weight of these elements and a smooth curve was drawn through the points. The bond distance in ZrI₃ was taken from this plot. The bond angle was assumed to be 101°. The individual moments of inertia are: I_A = I_B = 1.8520 X 10⁻⁵⁷ gm. cm.², I_C = 3.3661 X 10⁻⁵⁷ gm. cm.².

Force constants for ZrI₃ were estimated from those of the triiodides of phosphorus and arsenic. These were used in a valence force field calculation giving ω₁ = 185, ω₂ = 88, ω₃ = 181, and ω₄ = 65 cm.⁻¹. For the fluorides and chlorides of P, As, and Sb, ω₁ is greater than ω₃ but there appears to be a reversal as one goes to the bromides and iodides with ω₃ becoming greater than ω₁. An empirical correlation procedure for ZrI₃ gave ω₁ = 195, ω₂ = 90, ω₃ = 220, and ω₄ = 65 cm.⁻¹ in which ω₃ > ω₁. Since ω₃ > ω₁ for PI₃ and AsI₃, the correlation value for ω₃ was used to represent this frequency in ZrI₃.

TITANIUM TETRAIODIDE (TiI₄)

(CRYSTAL)

GFW = 555.5176

$$\Delta H_f^\circ = -89.3 \pm 2.0 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = -89.8 \pm 2.0 \text{ kcal/mol}$$

$$\Delta H^\circ = 2.37 \pm 0.15 \text{ kcal/mol}$$

$$\Delta H_m^\circ = 4.74 \pm 0.15 \text{ kcal/mol}$$

$$S^\circ_{298.15} = 88.8 \pm 1.6 \text{ gibbs/mol}$$

$$T_f = 379^\circ\text{K}$$

$$T_m = 428^\circ\text{K}$$

Heat of Formation

The heat of formation of TiI₄(c) was measured by Johnson et al. (1), based on the heats of hydrolysis of TiBr₄(c) and TiI₄(c) in sulfuric acid. These data result in a heat of reaction of -57.88 kcal/mol for the process TiI₄(c) + 2Br₂(l) = TiBr₄(c) + 2I₂(c), when recalculated with revised values of ΔHf° for HBr(aq) and HI(aq) (2). Combination of ΔHf°₂₉₈ with auxiliary JANAF data gives the adopted value of ΔHf°₂₉₈.

Heat Capacity and Entropy

King et al. (3) reported the heat capacity and enthalpy of TiI₄(c) over the temperature range 51° to 428°K. The value of S°₂₉₈ is calculated from these data based on S°₅₁ = 14.62 eu. The value of H°₅₁ - H°₀ is calculated to be 0.358 kcal/mol from a Debye-Einstein extrapolation of the measured heat capacities.

Transition Data

A first order transition was observed by King et al. (2) at 379°K. They reported the measured value of 2.37 kcal/mol, noting that this value had an uncertainty of 0.15 kcal/mol due to hysteresis in the transition.

Melting Data

The melting temperature and heat of melting were reported by King et al. (2). The large uncertainty on ΔHm° is due to the uncertainty and close proximity of the transition at 379°K.

Titanium Tetraiodide (TiI₄)

(Liquid) GFW = 555.5176

TITANIUM TETRAIODIDE (TiI₄)

(LIQUID)

GFW = 555.5176

 $\Delta H_f^\circ = \text{unknown}$ $\Delta H_f^\circ_{298.15} = -83.25 \text{ kcal/mol}$ $\Delta H_m^\circ = 4.74 \pm 0.15 \text{ kcal/mol}$ $\Delta H_v^\circ = 13.50 \pm 0.5 \text{ kcal/mol}$ $S^\circ_{298.15} = 74.532 \text{ gibbs/mol}$ $T_m = 428^\circ\text{K}$ $T_b = 652.6^\circ\text{K}$

Heat of Formation

The heat of formation of $\text{TiI}_4(l)$ is calculated from the heat of melting, ΔH_m° , the heat of formation of $\text{TiI}_4(c)$, and the values of $H_{428}^\circ - H_{298.15}^\circ$ for both crystal and liquid.

Heat Capacity and Entropy

King et al. (1) reported the enthalpy of $\text{TiI}_4(l)$ above the melting temperature. The heat capacity derived from these data is constant. The entropy, S°_{298} , of $\text{TiI}_4(l)$ is calculated from ΔS_m° and the values of $S_{428}^\circ - S_{298.15}^\circ$ of both crystal and liquid.

Melting Data

The melting temperature and heat of melting were reported by King et al. (1).

Vaporization Data

The boiling temperature, T_b , is taken as the point at which $K_p = 1$ for the reaction $\text{TiI}_4(l) = \text{TiI}_4(g)$. The heat of vaporization is calculated as the difference between ΔH_f° of the liquid and gas at the boiling temperature. The vapor pressure data are discussed in the table for $\text{TiI}_4(g)$.

Vibrational Frequencies and Degeneracies
 $\frac{\omega_e}{\text{cm}^{-1}}$
[175] (1) [260] (3) [55] (2) [69] (3)

Bond Distance: Ti-I = [2.5] Å

Bond Angle: I-Ti-I = [109°28']

 $\sigma = 12$ Product of the Moments of Inertia: $I_A I_B I_C = [4.33 \times 10^{-110}] \text{ g cm}^6$

Heat of Formation

The heat of formation of TiI₄(g) is calculated from that of TiI₄(l) and the heat of vaporization of the liquid. Blocher and Campbell (1) reported vapor pressure data for TiI₄(l) over the temperature range 473° to 655°K. Second and third law analyses of these data give values for ΔH_f° of 17.2 ± 0.1 and 16.98 kcal/mol, respectively, the third law drift being -0.4 ± 0.2 eu. The adopted value of ΔH_f° is based on the third law heat of vaporization.

Heat Capacity and Entropy

The interatomic distances are estimated from those of TiBr₄(c), TiBr₄(g) and TiI₄(c) (2). The tetrahedral model is assumed by analogy with TiCl₄(g) and TiBr₄(g). The principal moments of inertia are: $I_A = I_B = I_C = 3.51 \times 10^{-37} \text{ g cm}^2$. The vibrational frequencies of TiI₄(g) have been estimated by Ushanova et al. (3). The given estimates are based on their predictions and valence force field calculations.

ZIRCONIUM TETRAIODOIDE (ZrI₄) (CRYSTAL) MOL. WT. = 598.86

$$\Delta H_f^0 = [-115.4] \pm 1.0 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -115.9 \pm 0.8 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -115.9 \pm 0.8 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = -115.9 \pm 0.8 \text{ kcal. mole}^{-1}$$

T_g = 704°K.
Heat of Formation.

A. O. Turnbull, J. Phys. Chem. 65, 1652 (1961), measured the heat of reaction for the following reactions:

Turnbull used the same procedure to calculate the heat of formation of zirconium tetraiodide as he did for zirconium tetrabromide [see ZrBr₄ table]. The heat of formation of the solid zirconium tetraiodide from reaction (1) was -115.6 ± 0.8 kcal. mole⁻¹ and from reaction (2) was -116.3 ± 0.8 kcal. mole⁻¹. An average of these was taken as the heat of formation of the tetraiodide.

Heat Capacity and Entropy.

The heat capacity from 0 to 300°K. was calculated in the same manner as for ZrBr₄(c) [see ZrBr₄(c) table]. The values, q_p⁰ = 60°K. and q_p⁰ = 115°K. were used in the analysis. The value, a = 1.5 X 10⁻³, was obtained from a consideration of the sublimation calculations [see below]. The heat capacity above 300°K. represents a graphical extrapolation.

Melting.

T_m = 772°K. was reported by O. Rahlfs and W. Fischer, Z. anorg. allgem. Chem. 211, 349 (1933).

Sublimation Data.

Vapor pressure measurements have been reported by Rahlfs and Fischer (loc. cit.). Four values of "a" were used to compute the thermodynamic functions of the solid. That value of "a" was chosen which gave agreement between 2nd and 3rd law values for the heat of sublimation. The sublimation results for the four values of "a" are given in the following table.

"a"	ΔH _g (298) [3rd law]	ΔH _g (298) [2nd law]
3.0 X 10 ⁻³	29.99 kcal. mole ⁻¹	31.65 kcal. mole ⁻¹
2.5 X 10 ⁻³	30.39 kcal. mole ⁻¹	31.34 kcal. mole ⁻¹
2.0 X 10 ⁻³	30.76 kcal. mole ⁻¹	31.17 kcal. mole ⁻¹
1.5 X 10 ⁻³	31.02 kcal. mole ⁻¹	31.04 kcal. mole ⁻¹

A temperature dependent third law heat of sublimation at 298°K. was obtained for "a" = 3.0 X 10⁻³; this temperature trend decreased for smaller values of "a" and there was essentially no temperature dependence for "a" = 1.5 X 10⁻³. Various high temperature extrapolations were not used since, by experience with ZrBr₄(c), they produced insignificant changes in the heat values. The heat of sublimation was taken to be 31.0 kcal. mole⁻¹ since the entire analysis was conducted to obtain 2nd and 3rd law agreement.

From experience with a number of other compounds, that were found to be amenable to the theoretical treatment used here, the value "a" = 1.5 X 10⁻³ appears to be rather low, but no further analysis was deemed practical since all parameters for the gas and solid are estimated.

The sublimation point obtained from the free energy crossover of solid and gas was 703°K. The value reported by Rahlfs and Fischer (loc. cit.) was 704°K. The sublimation point was taken as 704°K.

Since the sublimation point is lower than the melting point, the liquid phase is thermodynamically unstable under ordinary conditions.

$$\text{Product of the Moments of Inertia: } I_A I_B I_C = [6.5718 \times 10^{-11}] \text{ gm}^3 \text{ cm}^6$$

Heat of Formation

Calculated from the heats of formation and sublimation for the crystal at 298.15°K. (see crystal table for details).

Heat Capacity and Entropy

The interatomic distance was obtained from an involved correlation of the interatomic distances and covalent radii of the tetrahalides of Pb, Si, Ti, Ge, and Sn. I. N. Godnev, A. M. Aleksandrovskaya, and I. V. Regina, Optics and Spectroscopy 2, 172 (1959), estimated the interatomic distance and report 2.67 Å as the Zr-I distance. The I-Zr-I angle was taken as the tetrahedral angle. The three principal moments of inertia are: $I_A = I_B = I_C = 4.0355 \times 10^{-37} \text{ gm. cm}^2$.

The fundamental vibrational frequencies are estimated. The product of ω_1 and internuclear distance for the tetrahalides of Pb, Ti, Ge, and Sn was found to be approximately constant. Using the estimated Zr-I internuclear distance a value of 147 cm^{-1} was obtained for ω_1 . Plots of ω_1 and ω_2 versus internuclear distance for these molecules were constructed and smooth curves drawn through the points. Values of ω_1 and ω_2 for ZrI₄ were read off from these plots; they were 146 cm^{-1} and 44 cm^{-1} respectively. Using $\omega_1 = 146 \text{ cm}^{-1}$ and $\omega_2 = 45 \text{ cm}^{-1}$, $\omega_3 = 237 \text{ cm}^{-1}$ and $\omega_4 = 58 \text{ cm}^{-1}$ were obtained from a valence force field calculation. Godnev, Aleksandrovskaya, and Regina (loc. cit.) estimated the vibrational frequencies and reported $\omega_1 = 152 \text{ cm}^{-1}$, $\omega_2 = 44 \text{ cm}^{-1}$, $\omega_3 = 211 \text{ cm}^{-1}$ and $\omega_4 = 55 \text{ cm}^{-1}$.

Liquid
Ideal Monatomic Gas

0°K. to 336.35°K.

336.35°K. to 1043.7°K.

1043.7°K. to 8000°K.

Heat of Formation.

Zero by definition.

Heat Capacity of Crystal.

Low temperature heat capacity measurements have been reported by I. M. Roberts [Proc. Phys. Soc. (London) 70B, 744-52 (1957)] (1.5°-20°K), by C. A. Krier, R. S. Craig, and W. E. Wallace [J. Phys. Chem. 61, 522 (1957)] (12°-320°K), by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas [Proc. Roy. Soc. (London), A233, 214 (1955)] (20°-350°K), by F. Simon and M. Zeidler [Z. physikal. Chem. 123, 383 (1926)] (15°-300°K), and by E. D. Eastman and W. H. Rodebush [J. Am. Chem. Soc. 40, 489 (1918)] (70°-230°K). A smooth curve was drawn through a large scale plot of the data, giving the most weight to the first three references. Above 300°K, the heat capacity data were adjusted to join smoothly with the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)].

Heat Capacity of Liquid and Heat of Melting.

The heat of melting and liquid heat capacity are from the heat content measurements of T. B. Douglas, A. F. Ball, D. C. Ginnings, and W. D. Davis (loc. cit.).

Heat of Sublimation, Ideal Gas Functions.

See tables for K(g) and K₂(g) for details.

POTASSIUM (K)

(LIQUID)

MOL. WT. = 39.100

$$\Delta H_f^{\circ} 298 = 0.546 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{\circ} = 0.558 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{\circ} = 18.38 \text{ kcal. per formula weight}$$

$$T_m = 336.35^{\circ}\text{K.}$$

$$T_b = 1037^{\circ}\text{K.}$$

Heat of Formation.

Back calculated from the heat of melting and the heat contents of solid and liquid at the melting point.

Heat of Melting and Heat Capacity.

The heat of melting, melting point, and liquid heat capacity were measured by T. B. Douglas, A. P. Ball, D. C. Glinings, and W. D. Davis [J. Am. Chem. Soc. 74, 2472 (1952)]. The heat capacity curve was extrapolated back to 298°K. and up to 2000°K. in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Potassium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1037°K. The vapor composition at this temperature is 94.5 mole % monatomic and 5.5 mole % diatomic gas. The heat of vaporization of 39.1 grams of liquid potassium to this equilibrium mixture is 18.38 kcal. See also tables for K(g) and K₂(g).

Thermodynamic Functions.

Thermodynamic functions were calculated using electronic levels and multiplicities from P. Risberg [Arkiv. Fysik 10, 585 (1956)] and C. E. Moore [Nat. Bur. Standards Circ. 467 (1949)]. Higher levels were averaged. The results are in excellent agreement with W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards 55, 83 (1955)].

Heat of Formation.

Evans, Munson, and Wagman (loc. cit.) have reviewed the vapor pressure data on potassium. Their calculations were revised slightly for the changes made in the functions for the condensed state. In addition, the recent data of W. M. Hakansi, M. Hadsen, W. A. Selke, and C. F. Bonilla [J. Phys. Chem. 60, 138 (1956)] were considered in selecting the heat of sublimation of 21.31 ± 0.20 kcal. mole⁻¹. A review of the properties of potassium vapor using imperfect gas theory to establish the dimer dissociation energy has recently been published by R. J. Thorn and G. H. Winslow [J. Phys. Chem. 65, 1297 (1961)]. Although the imperfect gas treatment appears to be favored by the experimental data available, this could not be unequivocally established. Unpublished vapor pressure data cited by Thorn and Winslow are in agreement with the values selected here, assuming ideal gas behavior.

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic potassium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels", Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation $K(\text{ref. state}) = e^-(\text{ref. state}) = K^+(\text{monatomic gas})$, thus K^+ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore, loc. cit.

POTASSIUM MONOXIDE (KO)

(IDEAL GAS)

GFW = 55.1014

Ground State Configuration [2π]

ΔH_f^o = [17.4 ± 1.0] kcal/molS_{298.15}^o = [56.9 ± 0.5] gibbs/molΔH_f^o₂₉₈ = [17.0 ± 1.0] kcal/mol

Electronic Levels and Quantum Heights

$$\frac{e_i, \text{ cm}^{-1}}{0} = \frac{g_i}{[4]}$$

$$\omega_e x_e = [350] \text{ cm}^{-1}$$

$$B_e = [0.3088] \text{ cm}^{-1}$$

$$\omega_e x_e = [2.2] \text{ cm}^{-1}$$

$$a_e = [0.0027] \text{ cm}^{-1}$$

$$\sigma = 1$$

$$r_e = [2.21] \text{ Å}$$

Heat of Formation

Brewer and Margrave (1) suggested that the ΔH_f^o value for KO(g) from the gaseous ions can be taken as the mean of the corresponding ΔH_f^o values for the alkali fluoride and chloride with a maximum uncertainty of 10 kcal/mol. We obtain the values ΔH_f^o = -137.94 and -117.7 kcal/mol for the reactions K⁺(g) + F⁻(g) = KF(g) and K⁺(g) + Cl⁻(g) = KCl(g), respectively. Assuming ΔH_f^o = -127.83 kcal/mol for the reaction K⁺(g) + O⁻(g) = KO(g), we calculate ΔH_f^o₂₉₈(KO, g) = 19.0 kcal/mol with the JANAF auxiliary values for the gaseous ions.

Based on the assumption that D₀(KO) = 1/2(D₀(K₂) + D₀(O₂)), or ΔH_f^o = 64.9 kcal/mol for the reaction KO(g) = K(g) + O(g), we evaluate ΔH_f^o₂₉₈(KO, g) = 15.6 kcal/mol or ΔH_f^o₂₉₈(KO, g) = 15.2 kcal/mol.

According to Somayajulu (2), in a sequence of similar diatomic molecules, k_rv_e/D₀ = constant, where k_r = force constant, r_e = equilibrium bond distance and D₀ = dissociation energy. Using r_e = 1.62 Å, D₀ = 77.9 kcal/mol for LiO(g), r_e = 2.2 Å and k_r(KO)/r_e(LiO) = 0.3015, we calculate D₀ = 55 kcal/mol for KO(g), yielding ΔH_f^o₂₉₈(KO, g) = 26.1 kcal/mol. The value k_r is derived from the relation k_r = 4π²ν²μ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass. The value of ΔH_f^o₂₉₈(KO, g) is tentatively adopted as 17 ± 10 kcal/mol.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for the OH(g) molecule, which has the same number of valence electrons. The values of ω_e and ω_ex_e are estimated by comparison with those for LiF(g) and KF(g). The bond distance is estimated from those for HO(g), HF(g) and KF(g). B_e and a_e are derived from r_e, ω_e and ω_ex_e by the method suggested by Herzberg (3).

Dec. 31, 1967

(IDEAL GAS)

POTASSIUM MONOXIDE UNINEGATIVE ION (K⁰⁻)

GFW = 55.10195

Ground State Configuration [1²]ΔH_f^o = [-33 ± 20] kcal/molS_{298.15} = [54.1 ± 0.3] gibbs/molΔH_f^o_{298.15} = [-33 ± 20] kcal/mol

Electronic Levels and Quantum Weights

$$\frac{g_i}{g_o} \frac{\omega_i}{\omega_o} = \frac{g_i}{g_o} \frac{\omega_i}{\omega_o}$$

$$\omega_i = [360] \text{ cm}^{-1}$$
$$\omega_o = [0.0027] \text{ cm}^{-1}$$
$$\sigma = 1$$
$$\tau_o = [2.2] \text{ Å}$$

Heat of Formation

The electron affinity (E. A.) of K⁰⁻(g) is unavailable, therefore the value of ΔH_f^o(K⁰⁻, g) is estimated. Assuming that the enthalpy change (ΔH_f^o) of the reaction (1) K⁰⁻(g) = K(g) + O²⁻(g) is approximately the average of the ΔH_f^o value for the reaction (2) K⁰⁻(g) = K(g) + O(g) and (3) K⁰⁻(g) = K(g) + F(g), we obtain ΔH_f^o = 1/2(63.5 + 117.3) = 90.4 kcal/mol for reaction (1). However, we compare the ΔH_f^o values for the reactions (4) HO(g) = H(g) + O(g), (5) HO⁻(g) = H(g) + O⁻(g), and (6) HF(g) = H(g) + F(g), and find that ΔH_f^o for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔH_f^o values for reactions (4) and (6). Based on this fact we estimated ΔH_f^o = 80 kcal/mol for reaction (1), yielding ΔH_f^o(K⁰⁻, g) = -33 kcal/mol. The value of ΔH_f^o(K⁰⁻, g) is tentatively adopted as -33 ± 20 kcal/mol. The electronic affinity of K⁰⁻(g) is derived to be 2.2 ± 0.8 eV. The value of E. A. for HO(g) is determined as 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of KF(g) which is isoelectronic with K⁰⁻(g). The values of ω_i, ω_o, x_i, and x_o are estimated by comparison with those for KF(g). The values of B_e and α_e are calculated from r_e, ω_e and ω_ex_e using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc. New York, 1950. The enthalpy at 0°K is -2.303 kcal/mol.

Thermodynamic Functions.

Spectroscopic data are the same as that selected by W. H. Evans, T. R. Munson, and D. D. Wagman [J. Research Natl. Bur. Standards **55**, 65 (1955)]. The calculated functions are in excellent agreement with their results.

Heat of Formation.

The heat of dissociation selected by Evans, Munson, and Wagman (loc. cit.) was used with the previously adopted heat of sublimation of the monomer to derive the heat of formation.

K_2O

MOL. WT. = 94.20

(CRYSTAL)

DIPOTASSIUM MONOXIDE (K_2O)

$\Delta H^\circ_f 0 = \text{Unknown}$
 $S^\circ_{298.15} = [22.5 \pm 1.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H^\circ_f 298.15 = -86.8 \pm 0.5 \text{ kcal. mole}^{-1}$

$T_d = 1154^\circ K. (600 \text{ mm Hg})$

Heat of Formation.

$\Delta H^\circ_f 298.15$ was reported by M. Rengade, Ann. Chim. et phys. [8] 14, 540 (1908), based on the measurements of the heats of solution of K(c) and $K_2O(c)$ in H_2O . The same value of $\Delta H^\circ_f 298.15$ was also given by R. de Forcrand, Compt. rend. 159, 991 (1914).

Heat Capacity and Entropy.

Both C_p and $S^\circ_{298.15}$ were estimated by comparison with those of the $Na_2O(c)$.

Temperature of Decomposition.

T_d was taken from, "Data on Chemicals for Ceramic Use", National Research Council Bulletin 118 (1949).

Heat of Formation.

ΔH°_f 298.15 was reported by National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1952. The value was based on the measured decomposition pressure of K₂O₂(c) by M. Centner and M. Elmenthal, IX Congr. IUPAC, 3A, 201 (1955).

Heat Capacity and Entropy.

The heat capacities and S°_{298.15} were estimated by comparison with those for Na₂O₂(c), Na₂O(c), and K₂O(c).

Temperature of Melting.

T_m was reported by Centner and Elmenthal, loc. cit.

DIPOTASSIUM DIOXIDE (K₂O₂) (CRYSTAL) MOL. WT. = 110.20

ΔH°_f 0 = Unknown

S°_{298.15} = [27.0 ± 1.5] cal. deg.⁻¹ mole⁻¹

ΔH°_f 298.15 = -118.5 ± 1.0 kcal. mole⁻¹

ΔH°_m = Unknown

T_m = 763°K.

$$\Delta H_f^\circ 298.15 = 38.41 \pm 0.40 \text{ kcal. mole}^{-1} \text{ (Monatomic gas)}$$

$$\Delta H_f^\circ 298.15 = 50.41 \pm 0.30 \text{ kcal. mole}^{-1} \text{ (Diatomic gas)}$$

$$S_{298.15}^\circ = 6.954 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^\circ = 0.7171 \pm 0.0037 \text{ kcal. mole}^{-1}$$

$$T_m = 453.69^\circ\text{K}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacities have been reported by the following authors for the temperature ranges indicated: L. M. Roberts, Proc. Phys. Soc. **70**, 744 (1957), 1.5 to 20°K (Li 99.5% pure); F. Simon and R. C. Swain, Z. Phys. Chem. **B20**, 169 (1935), 18° to 300°K; D. L. Martin, Proc. Roy. Soc. **A251**, 444 (1960), 22° to 300°K (Li 99.95% pure); T. B. Douglas, L. R. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. **77**, 2144 (1955), 299° to 1200°K (Li 99.98% pure). Martin, in a series of determinations, found that C_p depended on the thermal history of the sample; a peak at roughly 107°K was ascribed to a martensitic transformation. There is excellent continuity between the results of Roberts and of Martin, while those of Martin and Douglas et al. differ by 1% at 300°K and have been smoothly joined. The values of Simon and Swain were not used as they were 5% lower than Martin's and did not show the peak at 107°K; also their values for Al_2O_3 , reported at the same time, are lower than recent measurements. Heat capacities between 1200°K and the normal boiling point were obtained from the heat content equation given by Douglas et al. between 420° and 900°K.

Melting.

Douglas et al. (loc. cit.) report the triple point to be 180.54°K, which is here adopted as the melting point since the densities of solid and liquid lithium at 180°K are not available for calculating dT_m/dP . The same authors give the heat of melting as 432.3 ± 2.2 abs. Joule g^{-1} .

Heat of Sublimation.

Lithium vapor contains an appreciable amount of dimer, whose heat of dissociation has been selected by W. H. Evans, R. Jacobson, T. R. Munson, and D. D. Wagman, J. Res. Natl. Bureau of Standards **55**, 83 (1955), from spectroscopic and molecular beam measurements to be 25.76 ± 0.10 kcal. mole⁻¹ at 0°K. This heat of dissociation, together with the thermodynamic functions calculated in this work, has been used to find the partial pressures of Li(g) and Li₂(g) from the measured total vapor pressures. H. Hartmann and R. Schneider, Z. anorg. allgem. Chem. **180**, 275 (1929), report values from 1204° to 1353°K; while M. Mencherat, C. Rendus **208**, 499 (1939), reports effusion measurements from 735° to 915°K. Mencherat's pressures are calculated on the assumption of monatomic vapor and have been recalculated to find the true total pressure. Effusion measurements by L. C. Lewis, Z. Physik **69**, 766 (1931), and A. Bogros, C. Rendus **191**, 560 (1950) and Ann. Phys. **17**, 199 (1952), have been disregarded. Mencherat considers them to be inaccurate because of impurities in the lithium used, and Lewis used a doubtful calibration method. Heats of sublimation to monatomic vapor calculated from the vapor pressures of Hartmann and Schneider and of Mencherat agree to within 2% and the average value has been adopted. The heat of sublimation of the dimer was then calculated using this value.

Li

LITHIUM (Li)

(LIQUID)

At. Wt. = 6.940

 $\Delta H_f^\circ 298.15 = 0.569 \text{ kcal. mole}^{-1}$ $S_{298.15}^\circ = 8.113 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_m^\circ = 0.7171 \pm 0.0035 \text{ kcal. mole}^{-1}$ $T_m = 453.69^\circ\text{K}$ $T_b = 1620^\circ\text{K}$ (equilibrium mixture) T_b (Monatomic gas) = 1639°K $\Delta H_v 1638 = 35.16 \text{ kcal. mole}^{-1}$

Heat of Formation.

Obtained from the heat of fusion by adding $H_{453.69}^\circ - H_{298.15}^\circ$ for the solid and subtracting $H_{453.69}^\circ - H_{298.15}^\circ$ for the liquid.

Heat Capacity.

The data of T. B. Douglas, L. F. Epstein, J. L. Dever, and W. H. Howland, J. Am. Chem. Soc. 77, 2144 (1955) were taken and extrapolated below T_m and above 1200°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K .

Vaporization.

Lithium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1620°K ; the vapor pressure of the monatomic gas reaches 1 atm. at 1639°K and the heat of vaporization to monatomic gas is $35.16 \text{ kcal. mole}^{-1}$. See also Li(crystal).

Heat of Formation.
Same as the heat of sublimation to the monatomic gas; see notes on Li(crystal).

Heat Capacity and Entropy.

The energy levels have been taken from C. E. Moore, "National Bureau of Standards Circular 467," U. S. Government Printing Office, Washington (1949) p. 9. Closely spaced levels have been averaged and the appropriate multiplicities assigned to the averages.

Li⁺

Lithium Unipositive Ion (Li⁺)

(Ideal Gas) At. Wt. = 6.940

LITHIUM UNIPOSITIVE ION (Li⁺) (IDEAL GAS)

Heat of Formation.

The heat of formation at 0°K. was obtained from that of the ideal monatomic lithium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation Li(ref. state) - e⁻(ref. state) = Li⁺(monatomic gas), thus Li⁺ involves the difference in enthalpies of two reference states as well as its own enthalpy.

Heat Capacity and Entropy.

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Dec. 31, 1960; Sept. 30, 1966; Dec. 31, 1966

LITHIUM NITRIDE (LIN)

(IDEAL GAS)

GFW = 20.9457

Ground State Configuration [3 Σ]

ΔH_f° = 80 ± 40 kcal/molS°_{298.15} = [49.7] gibbs/molΔH_f°_{298.15} = 80 ± 40 kcal/mol

Electronic Levels and Quantum Weights

$$\frac{\epsilon_i}{\epsilon_1}, \text{ cm}^{-1} = \frac{E_i}{[3]}$$

 $\omega_e = [700] \text{ cm}^{-1}$ $\omega_e x_e = [7] \text{ cm}^{-1}$ $\sigma = 1$ $B_e = [1.25] \text{ cm}^{-1}$ $\alpha_e = [0.0183] \text{ cm}^{-1}$ $r_e = [1.71] \text{ Å}$

Heat of Formation.

The adopted ΔH_f°_{298.15} = 80 ± 40 kcal/mol is calculated from the following estimates:

Method	D° kcal/mol	76	75	ΔH _f ° _{298.15} kcal/mol
Estimate D° from geometric mean for Li ₂ and N ₂				
Estimate from D° for series N ₂ (g), CN(g), and BeN(g)		40 - 100	110 - 50	
Estimate from D° for series HN(g), HO(g), LiF(g) and LiO(g)		20 - 60	130 - 90	

J. L. Margrave and P. Schapitanonda, J. Phys. Chem. 59, 1231 (1955), report estimated dissociation energies in the range 111-178 kcal/mol, based on approximate ionic binding energies calculated from ionic radii for N⁻ in the range 0.70 to 1.08 Å.

Heat Capacity and Entropy.

The molecular constants ω_e , r_e and $\omega_e x_e$ are estimated by comparison with those of CN, BN, CO, BO and LiO. The values of α_e and B_e are calculated from the above constants. The ground state configuration is assumed to be 3Σ by analogy with NH and OH⁺.

Lithium Nitroxide (LiON)
(Ideal Gas) $G^{\circ}F = 36.9451$

LiNO

OPW = 36.9451

(IDEAL GAS)

LITHIUM NITROXIDE (LiON)

Point Group C_{2v}

$S^{\circ}_{298.15} = 58.61$ gibbs/mol

Ground State Quantum Weight = [1]

$\Delta H^{\circ}_f = [43.5 \pm 10]$ kcal/mol
 $\Delta H^{\circ}_{298.15} = [43.0 \pm 10]$ kcal/mol

Vibrational Frequencies and Degeneracies

ω , cm^{-1}	
1350 (1)	
330 (1)	
650 (1)	

$O-N = 1.30 \pm 0.05 \text{ \AA}$

$\sigma = 1$

Bond Angle: $Li-O-N = 100 \pm 10^{\circ}$

Product of the Moments of Inertia: $I_A I_B I_C = 2.6523 \times 10^{-116} \text{ g}^3 \text{ cm}^6$

Heat of Formation

The heat of formation (ΔH°_{298}) for $LiON(g)$ has not been determined experimentally. The ΔH°_{298} value adopted is calculated from the estimated Li-O and O-N bond energies. The value, $D(Li-O) = 88$ kcal/mol, is obtained by averaging the bonds in $Li_2O(g)$. The value, $D(O-N) = 69$ kcal/mol, is calculated on the assumption that $D(ClON-O) = D(N-Of)$. The ΔH°_{298} of $LiOH(g)$, calculated similarly from bond energies (i.e. $D(Li-O) = 88$ kcal/mol and $D(O-H) = 111$ kcal/mol), is 10 kcal/mol more than the measured value. Therefore, we subtract 10 kcal/mol from the ΔH°_{298} of $LiON$, 53 kcal/mol, estimated from the above bond energies, and arrive at 43 kcal/mol for the adopted value.

Heat Capacity and Entropy

The vibrational frequencies, bond distances and bond angle were obtained from W. L. S. Andrews and G. C. Fimentel, loc. cit. The three principal moments of inertia are: $I_A = 1.2706 \times 10^{-56}$, $I_B = 3.9776 \times 10^{-39}$ and $I_C = 5.2482 \times 10^{-39} \text{ g cm}^2$.

Dec. 31, 1960 Mar. 31, 1964

LITHIUM MONOXIDE (LiO)

MOL. WT. = 22.940

(IDEAL GAS)

Ground State Configuration $[^2P]$
 $S_{298.15}^{\circ} = 50.395 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^{\circ} 0 = 20.1 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^{\circ} 298.15 = 20.1 \pm 5 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{\epsilon_i, \text{ cm.}^{-1}}{0} \frac{g_i}{4}$$

$\omega_e = 745 \text{ cm.}^{-1}$
 $\omega_e x_e = [4.835] \text{ cm.}^{-1}$
 $\alpha_e = [0.01288] \text{ cm.}^{-1}$
 $\sigma = 1$
 $r_e = [1.62] \text{ \AA}$

Heat of Formation.

D. White, K. S. Sehadri, D. P. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. **39**, 2463 (1963) calculated the heat of formation from their mass spectral data by two different methods.

For the first calculation (a) they combined the slope of the log Π vs $1/T$ curve for LiO^+ with the slopes for Li^+ and Li_2O^+ for the reaction $\text{Li}_2\text{O}^+ (\text{g}) \rightarrow \text{Li} (\text{g}) + \text{LiO} (\text{g})$. For the second calculation (b) they assumed a cross section $\sigma_{\text{LiO}}/\sigma_{\text{Li}_2\text{O}} = 1$ and from this they calculated a partial pressure for $\text{LiO} (\text{g})$ at 1500°K and an equilibrium constant for the reaction $\text{Li}_2\text{O} (\text{g}) \rightarrow \text{Li} (\text{g}) + \text{LiO} (\text{g})$. They obtained (a) $\Delta H_f^{\circ} 298 = 18.3 \text{ kcal. mole}^{-1}$ and (b) $\Delta H_f^{\circ} 298 = 16.3 \text{ kcal. mole}^{-1}$, and used the average value from the two methods for the heat of formation of $\text{LiO} (\text{g})$. The JANAF heat of formation, $20.1 \pm 5 \text{ kcal. mole}^{-1}$, was obtained in the same way using their data and the present tables i.e. (a) $\Delta H_f^{\circ} 298 = 22.0 \text{ kcal. mole}^{-1}$ and (b) $\Delta H_f^{\circ} 298 = 18.3 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The molecular constants, ω_e , x_e , α_e , and σ , were calculated from ω_e and r_e , reported by White et al. The ground state configuration, 2P , was estimated by J. S. Gordon, Thiokol Chemical Corp., Reaction Motor Division, Denville, N. J., "Thermodynamic Data for Combustion Products", January, 1960, by A. Buchler and J. L. Stauffer, J. Chem. Phys. **39**, 2299 (1963) and by White et al.

Dec. 31, 1967

LITHIUM MONOXIDE UNINEGATIVE ION (LiO⁻) (IDEAL GAS) GFW = 22.93895

Ground State Configuration [↑↓]
 $\Delta H_f^\circ = [-16 \pm 15] \text{ kcal/mol}$
 $\Delta H_f^\circ_{298.15} = [-16 \pm 15] \text{ kcal/mol}$

Electronic Levels and Quantum Weights

$\epsilon_i, \text{ cm}^{-1}$ $\frac{g_i}{O}$ $\frac{g_i}{[1]}$

$\omega_e x_e = [4.5] \text{ cm}^{-1}$ $\sigma = 1$
 $\omega_e = [1.360] \text{ cm}^{-1}$ $r_e = [1.6] \text{ \AA}$

Heat of Formation

Data on the electron affinity (E.A.) of LiO (g) are unavailable, therefore the value of $\Delta H_f^\circ(\text{LiO}^-, \text{g})$ is estimated. We first assume that the enthalpy change (ΔH_r°) of the reaction (1) $\text{LiO}^-(\text{g}) = \text{Li}(\text{g}) + \text{O}^-(\text{g})$ is close to the average of the ΔH_r° values for the reactions (2) $\text{LiO}(\text{g}) = \text{Li}(\text{g}) + \text{O}(\text{g})$ and (3) $\text{LiF}(\text{g}) = \text{Li}(\text{g}) + \text{F}(\text{g})$. The atom F(g) is isoelectronic with O⁻(g). In other words, the ΔH_r° for reaction (1) is approximately $1/2(76.91 + 135.84) = 106.4 \text{ kcal/mol}$. Then we compare the ΔH_r° values for the reactions (4) $\text{HO}(\text{g}) = \text{H}(\text{g}) + \text{O}(\text{g})$, (5) $\text{HO}^-(\text{g}) = \text{H}(\text{g}) + \text{O}^-(\text{g})$, and (6) $\text{HF}(\text{g}) = \text{H}(\text{g}) + \text{F}(\text{g})$, and find that ΔH_r° for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔH_r° values for reactions (4) and (6). Based on this fact we estimate $\Delta H_r^\circ = 96.4 \text{ kcal/mol}$ for reaction (1), yielding $\Delta H_f^\circ(\text{LiO}^-, \text{g}) = -15.5 \text{ kcal/mol}$.

Applying the difference in electron affinity between H(g) and Li(g) to OH(g) gives an approximate value, E. A. = 1.7 eV (39.2 kcal/mol) for LiO(g). The value of E. A. for H(g), Li(g) and OH(g) are taken from U. S. Bur. Std. Rept. 8628, Jan. 1, 1965. Based on $\Delta H_r^\circ = 39.2 \text{ kcal/mol}$ for the reaction $\text{LiO}^-(\text{g}) = \text{LiO}(\text{g}) + \text{e}^-(\text{g})$, we derive $\Delta H_f^\circ = -19.1 \text{ kcal/mol}$ for $\text{LiO}^-(\text{g})$, which is in reasonable agreement with the above estimated value.

The value of ΔH_f° for $\text{LiO}^-(\text{g})$ is tentatively adopted as $-16 \pm 15 \text{ kcal/mol}$. Using this ΔH_f° value, we derive E. A. = $1.6 \pm 0.7 \text{ eV}$ for LiO(g). The electron affinity of OH(g) is $1.8 \pm 0.1 \text{ eV}$.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of LiF(g) which is isoelectronic with LiO⁻(g). The values of ω_e , $\omega_e x_e$ and r_e are estimated by comparison with the observed data for LiF(g). The values of B_e and a_e are calculated from r_e , ω_e and $\omega_e x_e$ by use of the method suggested by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.137 kcal/mol .

LITHIUM, DIATOMIC (Li_2)

(IDEAL GAS)

MOL. WT. = 13.880

$\Delta H_f^0 = 50.298 \text{ kcal. mole}^{-1}$
Ground State Configuration Σ^+
 $\Delta H_f^0 = 50.298 \text{ kcal. mole}^{-1}$
 $S_{298.15}^0 = 47.050 \text{ cal. deg. mole}^{-1}$

$\omega_e = 353.59 \text{ cm}^{-1}$
 $\omega_e x_e = 2.625 \text{ cm}^{-1}$
 $\alpha_e = 0.00718 \text{ cm}^{-1}$
 $r_e = 2.673 \text{ \AA}$
 $d = 2$

Heat of Formation.
Same as the heat of sublimation to the diatomic gas; see notes on Li (crystal).

Heat Capacity and Entropy.

The spectroscopic constants of Li_2 listed by G. Herzberg, "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Co., Inc., New York (1950) have been corrected for the presence of 7.5% Li^6 in naturally occurring lithium, J. R. Stehn and E. P. Clancy, "Chart of the Nuclides", General Electric Co., Schenectady (1956).

$$\Delta H_f^\circ = 9.056 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_f^\circ = -143.1 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^\circ = 14 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^\circ = 9.056 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 1843^\circ \text{K.}$$

Dec. 31, 1960; Mar. 31, 1964

Heat of Formation.

The selected heat of formation was calculated as follows:

Reaction	ΔH _f ° 298.15 kcal. mole ⁻¹	Ref.
(I) Li ₂ O(c) + H ₂ O(l) = 2LiOH(∞H ₂ O)	-31.74 ± 0.08	(a)
(II) Li(c) + 1/2 O ₂ (g) = LiOH(∞H ₂ O)	-121.572 ± 0.019	(b)
(III) H ₂ (g) + 1/2 O ₂ (g) = H ₂ O(l)	-68.3174	(c)
(IV) 2Li(c) + 1/2 O ₂ (g) = Li ₂ O(c)	-143.1 ± 0.5	(d)
(a) V. F. Kolesov, S. M. Skuratov, and I. D. Zaklin, <i>Russian J. Inorganic Chemistry</i> , 3 , 558 (1959).		
(b) S. R. Gunn and L. G. Green, <i>J. Am. Chem. Soc.</i> , 80 , 4782 (1958).		
(c) F. D. Rossini, D. D. Wagman, W. H. Evans, S. Levine, and I. Jaffe, "Selected Values of Chemical Thermodynamic Properties" National Bureau of Standards Circular 500, 1952 (reprinted 1961).		
(d) Reaction (IV) is the sum of -(I) + 2(II) - (III).		

Kolesov, et al. (loc. cit.) measured the enthalpy of the reaction of Li₂O with water at 20° in 5 experiments.

The mean ΔH_f° was -31.41 ± 0.08 kcal. This was brought to 298°K by Kolesov using enthalpy data of (a) H. L. Johnston and T. W. Bauer, *J. Am. Chem. Soc.*, **73**, 1119 (1951), for Li₂O, (b) N. S. Osborne, J. F. Stinson, and D. C. Ginnings, *J. Res. Natl. Bur. Stems*, **A**, **23**, 197 (1959) for H₂O, (c) F. T. Quaker and K. N. Schmarke, *J. Am. Chem. Soc.*, **55**, 1013 (1933) for C_p of LiOH(aq) and (d) Rossini, et al., (loc. cit.) for aqueous LiOH. In addition to the above, N. N. Beketov, *Bull. Acad. Sci. Russ. Ser. 32, 186 (1888) and H. R. Forrester, *Compt Rend.*, **144**, 1403 (1907) have reported experimental heats for Li₂O. Rossini et al. and Johnston and Bauer have reported heats of formation for Li₂O recalculated from older data. L. G. Panolino, in a Natl. Research Corp. Quarterly Report, July 1 to Sept. 30, 1962, reported a ΔH_f° 298 of -141.1 ± 4.2 kcal. He measured the heat of combustion of Li(c) in O₂(g) in a Parr bomb.*

Heat Capacity and Entropy.

The low temperature C_p data of H. L. Johnston and T. W. Bauer, (loc. cit.) from [17° -298°K.] was joined graphically to the high temperature C_p data of C. H. Shomate and A. J. Cohen, *J. Am. Chem. Soc.*, **77**, 285 (1955) [425°-1045°K.] and E. N. Rodgina, and K. A. Gomelakli, *Russian J. Phys. Chem.*, **35**, 898 (1961) [370°-1125°K.]. The S°_{298.15} was reported by Johnston and Bauer using S°₁₆ (extrap.) = 0.003 cal. deg.⁻¹ mole⁻¹.

Melting Data.

The melting point of Li₂O is uncertain. The selected melting point, 1843°K., was measured by A. E. van Arkel, E. A. Flood, and N. F. H. Bright, *Can. J. Chem.*, **31**, 1009 (1953). L. Brewer and J. L. Margrave, *J. Phys. Chem.*, **59**, 421 (1955) reported the melting point 1700°K. They also stated that H. van Konster and F. Jaeger, *Proc. Roy. Acad. Sci., Amsterdam*, **16**, 857 (1914) had reported 1700° (1973°K) as the melting point. The heat of melting, [14] kcal. mole⁻¹, was estimated by A. Glaesner, "The Thermochemical Properties of the Oxides, Fluorides, and Chlorides to 2500°K.", Argonne National Laboratory, University of Chicago, ANL-5750, 1957.

Heat of Sublimation.

Li₂O(c) vaporizes to Li₂O(g), LiO(g), Li₂O₂(g), Li(g), and O₂(g) [J. Berkhovitz, W. A. Chupka, G. D. Blue and J. L. Margrave, *J. Phys. Chem.*, **63**, 644 (1959); D. White, K. S. Sehadri, D. F. Dever, D. E. Mann, and M. J. Linevsky, *J. Chem. Phys.*, **39**, 2465 (1963); D. L. Hildenbrand, W. F. Hall, and N. D. Potter, *J. Chem. Phys.*, **39**, 296 (1963); D. L. Hildenbrand, L. P. Theard, W. F. Hall, and N. D. Potter, Fifth Quarterly Technical Report, U-2289, Aeronutronic Division of Philco Corporation, 15 September 1963; L. P. Firsova and A. N. Nesmeyanov, *Russian J. Phys. Chem.*, **34**, 1232 (1960)]. The major species (0°-1700°K.) are reported to be Li₂O(g), Li(g), and O₂(g) with lesser amounts of LiO(g) and Li₂O₂(g). Hildenbrand, et al., U-2289, have reported about equal amounts of Li₂O⁺ and Li⁺ (1300 to 1550°K.) and about 1/30th of this amount of LiO⁺. White, et al., calculated ΔH_{sub} from their mass spectra data. They made two different calculations (a) for Li₂O(c) → Li₂O(g) and (b) for Li₂O(g) → 2Li(g) + 1/2 O₂(g), and found (a) 102.5 kcal. and (b) 99.0 kcal. They used a weighted average of (a) and (b) and obtained 101.6 kcal. at 0°K. The selected ΔH_{sub}° 298 of 102.5 ± 3 kcal. was obtained in the same manner using their data and the present JANAF functions, 1.e. (a) 104.2 kcal. and (b) 100.3 kcal. Knudsen-effusion data of White et al., corrected for dissociation pressure with JANAF values gives Li₂O pressures slightly different than those reported. The recalculated pressures give a 3rd law ΔH_{sub}° 298 of 101.7 kcal. for both cells. The corresponding 2nd law values are 85 and 95.5 kcal. for cell 7 and 8. The 3rd law treatment of both sets of data show relatively large trends of ΔH_{sub} with T which are probably too large to be only due to errors in the functions. (Continued on Lithium Oxide Li₂O(g) table)

S_{298.15} = 13.160 cal. deg.⁻¹ mole⁻¹
 ΔH_f° 298.15 = -132.129 kcal. mole⁻¹
 ΔH_m° = [14] kcal. mole⁻¹
 ΔH_v° = Unknown

T_m = 1843°K.

T_b = [2838°K.]

Heat of Formation.

ΔH_f° (l) was obtained from ΔH_f° (c) by adding ΔH_m and the difference between H₁₈₄₃-H₂₉₈ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated at 8 cal. deg.⁻¹ g. atom⁻¹ from comparisons with similar compounds and from Kopp's rule. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See melting data given on the Li₂O crystal table.

Vaporization Data.

The vapor over Li₂O(c) at 1700°K. is composed of Li₂O(g), Li(g), O₂(g), LiO(g), and Li₂O₂(g). Thus a boiling point becomes almost meaningless. The value, 2836°K. listed above is the temperature at which the free energy of Li₂O(g) and the free energy of Li₂O(l) are equal. L. Brewer, Chem. Rev. 52, (1953) estimated a boiling point of 2600°K.

Bond Distances: Li-O = [1.59] Å

Bond Angle: Li-O-Li = 180°

Rotational Constant: B₀ = 0.46045 cm.⁻¹

Heat of Formation.

The heat of formation was calculated from the heat of formation of the crystal and the heat of sublimation.

Heat Capacity and Entropy.

D. White, K. S. Seshairi, and D. P. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. 39, 2463 (1963) made an estimate of the bond distance Li-O = 1.59 Å based on an analysis of their vibrational spectra. They found that Li₂O was a linear molecule. A. Buchler and J. L. Stauffer, J. Chem. Phys. 39, 2299 (1963) have shown from electric deflection experiments that Li₂O is very probably linear. They also report from the results of an effusion experiment evidence that the electron diffraction data and Li-O bond distance, 1.82 Å reported by F. A. Akishin and N. G. Rambidi, Dokl. Akad. Nauk. SSSR 118, 973 (1958) [English Translation, Proc. Acad. Sci. USSR, Phys. Chem. Sect. 118, 83 (1958)] are for Mo-O in Li₂MoO₄ rather than for Li-O in Li₂O. Buchler and Stauffer (loc. cit.) estimate an Li-O distance of 1.55 Å. White, et al., (loc. cit.) have estimated the vibrational frequencies ν₁ = [760] cm.⁻¹ and ν₂ = [140] cm.⁻¹ and assigned ν₃ = 987 cm.⁻¹ from their infrared matrix spectra. The principal moments of inertia calculated from the molecular constants are: I_A = 0, and I_B = I_C = 5.8256 X 10⁻³⁹ g. cm.².

Heat of Sublimation (continued from Li₂O(c) table).

A sample of LiAlO₂ was melted 7 times in argon in an arc-image furnace, H. Prophet, "Melting Point of Lithium Aluminate", ARPA-1-150, Dow Chemical Co., Mar. 9, 1961. The sample decomposed on fusion and successive melting points approached that of Al₂O₃. The residue was found to be 95% Al₂O₃ and 5% LiAl₂O₆. The sample and residue were characterized by X-ray diffraction. A reasonable assumption from this is that ΔF₂(3000°K) = 0 for 2LiAlO₂(c) = Al₂O₃(c) + Li₂O(g). From this ΔF₂, a ΔH_f^o 298 for Li₂O of 50 kcal. was calculated. A vapor pressure study of the molecular species over the decomposing LiAlO₂ might help resolve the discrepancies in lithium oxide ΔH_f^o values.

ΔH_f° = Unknown

ΔH_f° 298.15 = -151.2 ± 2.0 kcal. mole⁻¹

S° 298.15 = [13.5 ± 1.0] cal. deg⁻¹ mole⁻¹

T_d = 468°K.

Heat of Formation.

ΔH_f° 298.15 was reported by R. de Forcrand, Compt. rend. 130, 1465 (1900), based on the measured heats of the reactions of $\text{Li}_2\text{O}_2(\text{c})$ with $\text{HCl}(\text{aq.})$ and $\text{LiOH}(\text{aq.})$ with $\text{H}_2\text{O}_2(\text{aq.})$.

Heat Capacity and Entropy.

Both C_p and S°_{298.15} were estimated by comparison with those of the $\text{Na}_2\text{O}_2(\text{c})$, respectively.

Temperature of Decomposition.

T_d was reported to be about 300°C. by N. M. Wiederhorn, N. F. Surprenant, and A. J. Lefrier, "Research on New Methods of Separation of Air into O₂ and N₂ Components," C-53825, First-Quarterly Progress Report, September 1961, Arthur D. Little, Inc. The value adopted was reported by Bulletin of the National Research Council, No. 118, "Data on Chemicals for Ceramic Use", June, 1949, obtained from M. Centnerzwer and M. Blumenthal, Bull. intern. acad. polonaise, Classe. sci. math. nat., A 499 (1933).

Heat of Formation.

The heat of formation, -58 kcal., was calculated from an equilibrium constant for the reaction $\frac{1}{2} \text{O}_2(\text{g}) + \text{Li}_2\text{O}(\text{g}) \rightarrow \text{Li}_2\text{O}_2(\text{g})$ and the current JANAF functions. The equilibrium constant, 0.39, was estimated by D. White, K. S. Seshadri, D. F. Dever, and D. E. Mann, and M. J. Linevsky, J. Chem. Phys. **39**, 2465 (1965), from their mass spectrometric data.

Heat Capacity and Entropy.

White, et al., (loc. cit.), from their spectral data have assigned two observed frequencies and estimated the remaining frequencies using the ionic model calculations of J. Berkowitz, J. Chem. Phys. **29**, 1386 (1958); **32**, 1519 (1960) as a guide. They proposed a planar rhombic structure of D_{2h} symmetry, similar to the alkali halide dimers, for the previously undetected Li₂O₂ molecule, and estimated the angle, 116°, and bond distance, 1.90 Å, from their matrix spectra. The principal moments calculated from these molecular constants are: $I_A = 13.793 \times 10^{-39}$, $I_B = 2.356 \times 10^{-39}$, and $I_C = 16.129 \times 10^{-39} \text{ g. cm.}^2$.

(CRYSTAL)

LITHIUM METASILICATE (Li_2SiO_3)

GFW = 89.9622

$\Delta \text{H}^o_{\text{f}} = -391.63 \pm 1.0 \text{ kcal/mol}$
 $\Delta \text{H}^o_{\text{f}} 298.15 = -394.24 \pm 1.0 \text{ kcal/mol}$
 $\Delta \text{H}^o = 6.7 \pm 0.5 \text{ kcal/mol}$

$S^o_{298.15} = 19.19 \pm 0.3 \text{ gibbs/mol}$

$T_m = 1474 \pm 1^\circ \text{K}$

Heat of Formation

The heats of solution of $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{SiO}_3(\text{c})$ in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kresak, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). The authors derived two values of $\Delta \text{H}^o_{\text{f}}$ of $\text{Li}_2\text{O}(\text{c})$ from those of $\text{LiCl}(\text{c})$ and $\text{Li}_2\text{SO}_4(\text{c})$, presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate $\Delta \text{H}^o_{\text{f}}$ of $\text{Li}_2\text{O}(\text{c})$ as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent $\Delta \text{H}^o_{\text{f}}$ values for $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{HCl}(\text{aq})$, $\text{H}_2\text{SO}_4(\text{aq})$, and $\text{Li}_2\text{O}(\text{c})$. The corresponding enthalpy changes, $\Delta \text{H}^o_{\text{f}}$, for the reaction $\text{Li}_2\text{O}(\text{c}) + \text{SiO}_2(\text{quartz}) = \text{Li}_2\text{SiO}_3(\text{c})$ are derived as -33.08 and -34.17 kcal/mol. Adopting the weighted average $\Delta \text{H}^o_{\text{f}} 298 = -33.44$ kcal/mol with $\Delta \text{H}^o_{\text{f}} 298(\text{Li}_2\text{O}, \text{c}) = -143.1$ kcal/mol and $\Delta \text{H}^o_{\text{f}} 298(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta \text{H}^o_{\text{f}} 298 = -394.24$ kcal/mol for $\text{Li}_2\text{SiO}_3(\text{c})$. This $\Delta \text{H}^o_{\text{f}} 298(\text{Li}_2\text{SiO}_3, \text{c})$ value is independent of future changes in $\Delta \text{H}^o_{\text{f}} 298$ of $\text{Li}_2\text{O}(\text{c})$ but the values of $\Delta \text{H}^o_{\text{f}}$ and ΔH^o are not independent.

The heats of solution of $\text{LiOH}(\text{c})$ and $\text{Li}_2\text{SiO}_3(\text{c})$ in 20 percent HF(aq) at 50°C were measured by W. E. Hatton, D. L. Hildenbrand, G. C. Sinke, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. The Li_2SiO_3 sample was prepared from lithium carbonate and silica by fusion under vacuum at 1500°C . Analysis gave 66.74 percent SiO_2 and 15.12 percent Li . The corresponding calculated values are 66.79 and 15.43. Also present were 0.5 percent K and 0.06 percent Na. Corrections were made for impurities in the heat of formation measurements. The results are given as follows:

$2\text{LiOH}(\text{c}, 25^\circ \text{C}) + 2\text{HF}(\text{sol}, 50^\circ \text{C}) + 2\text{LiF}(\text{sol}, 50^\circ \text{C}) + 2\text{H}_2\text{O}(\text{sol}, 50^\circ \text{C})$
 $\text{SiO}_2(\text{c}, 25^\circ \text{C}) + 6\text{HF}(\text{sol}, 50^\circ \text{C}) + \text{H}_2\text{SiF}_6(\text{sol}, 50^\circ \text{C}) + 2\text{H}_2\text{O}(\text{sol}, 50^\circ \text{C})$
 $3\text{H}_2\text{O}(\text{sol}, 50^\circ \text{C}) + 2\text{LiF}(\text{sol}, 50^\circ \text{C}) + \text{H}_2\text{SiF}_6(\text{sol}, 50^\circ \text{C}) + \text{Li}_2\text{SiO}_3(\text{c}, 25^\circ \text{C}) + 8\text{HF}(\text{sol}, 50^\circ \text{C})$
 $\text{H}_2\text{O}(\text{sol}, 50^\circ \text{C}) + \text{H}_2\text{O}(\text{f}, 25^\circ \text{C})$
 $2\text{LiOH}(\text{c}, 25^\circ \text{C}) + \text{SiO}_2(\text{c}, 25^\circ \text{C}) + \text{Li}_2\text{SiO}_3(\text{c}, 25^\circ \text{C}) + \text{H}_2\text{O}(\text{f}, 25^\circ \text{C})$

The $\Delta \text{H}^o_{\text{f}} 298$ for the second reaction was determined by D. R. Torgeson and T. G. Sahama, J. Am. Chem. Soc. 70, 2156 (1948). Based on the calculated enthalpy change for the overall reaction, $\Delta \text{H}^o_{\text{f}} 298 = -13.14$ kcal/mol and $\Delta \text{H}^o_{\text{f}} 298 = -115.84$, -217.7 and -88.32 kcal/mol for $\text{LiOH}(\text{c})$, $\text{SiO}_2(\text{low quartz})$, and $\text{H}_2\text{O}(\text{f})$, respectively, we derived $\Delta \text{H}^o_{\text{f}} 298(\text{Li}_2\text{SiO}_3, \text{c}) = -394.21 \pm 1.0$ kcal/mol, which is in agreement with the adopted value.

C. Kroger and E. Fingas, Z. Anorg. Allgem. Chem. 213, 12 (1933), measured the equilibrium pressure of CO_2 over a mixture of $\text{Li}_2\text{CO}_3(\text{c})$, $\text{SiO}_2(\text{quartz})$, and $\text{Li}_2\text{SiO}_3(\text{c})$ from 585 to 781°K . The enthalpy change ($\Delta \text{H}^o_{\text{f}} 298$) of the reaction $\text{Li}_2\text{CO}_3(\text{c}) + \text{SiO}_2(\text{c}) + \text{Li}_2\text{SiO}_3(\text{c}) + \text{CO}_2(\text{g})$ is evaluated by the second and third law methods to be 30.94 and 29.47 kcal/mol, respectively. Using $\Delta \text{H}^o_{\text{f}} 298 = -290.84$, -217.7 and -84.05 kcal/mol for $\text{Li}_2\text{CO}_3(\text{c})$, $\text{SiO}_2(\text{c})$ and $\text{CO}_2(\text{g})$, respectively, and third law $\Delta \text{H}^o_{\text{f}} 298$, we obtain $\Delta \text{H}^o_{\text{f}} 298(\text{Li}_2\text{SiO}_3, \text{c}) = -384.82 \pm 5$ kcal/mol, which is not used.

Heat Capacity and Entropy

The low temperature heat capacities, 25 - 340°K , were measured by Hatton et al., loc. cit., with an adiabatic vacuum calorimeter, using a nickel-plated copper sample container. During the filling and sealing of the calorimeter, the compound was handled in an anhydrous, CO_2 -free atmosphere so as to avoid contamination. The purity of the sample is not well established. The high temperature heat capacities are estimated by summation of the Cp's of the constituent oxides Li_2O and SiO_2 , and a subsequent correction based upon a comparison of the heat capacities of $\text{Na}_2\text{SiO}_3(\text{c})$ and its constituent oxides. These estimated Cp values are plotted, and the resulting curve is joined smoothly with the low temperature Cp curve at 298°K . The entropy, S^o_{298} , is derived using the measured low temperature heat capacities, based on $S^o_{25} = 0.023$ eu.

Melting Data

See $\text{Li}_2\text{SiO}_3(\text{l})$ table for details.

LITHIUM METASILICATE (Li_2SiO_3) (LIQUID)

$S_{298.15}^\circ = 22.958$ gibbs/mol

$\Delta H_{298.15}^\circ = -389.441$ kcal/mol

$\Delta H_m^\circ = 6.7 \pm 0.5$ kcal/mol

$T_m = 1474 \pm 1^\circ\text{K}$

Heat of Formation
 $\Delta H_{298}^\circ(t)$ is obtained from $\Delta H_{298}^\circ(c)$ by adding ΔH_m° and the difference between H_{1474}° - H_{298}° for crystal and liquid.
 Tschernobaeff, Rev. Met. 21, 729 (1905), measured the heat of reaction between SiO_2 and Li_2CO_3 in a bomb calorimeter, using carbon as the auxiliary combustible material. Based on the derived $\Delta H_{298}^\circ = 24.99$ kcal/mol for the reaction $\text{Li}_2\text{CO}_3(c) + \text{SiO}_2(c) \rightarrow \text{Li}_2\text{SiO}_3(\text{gl}) + \text{CO}_2(g)$, the heat of formation for $\text{Li}_2\text{SiO}_3(\text{gl})$ is evaluated as -389.30 kcal/mol, which is in fair agreement with the adopted value.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $\text{Na}_2\text{SiO}_3(l)$, $\text{Na}_2\text{O}(l)$ and $\text{Li}_2\text{O}(l)$. A glass transition is assumed at 1000°K; i.e., the heat capacities below 1000°K are taken to be the same as those for $\text{Li}_2\text{SiO}_3(c)$. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point has been reported as 1474 ± 1 and 1461°K by F. C. Kracek, J. Phys. Chem. 34, 2841 (1930), and H. S. Van Klooster, Z. Anorg. Chem. 89, 135 (1911), respectively. The value reported by Kracek is adopted.
 R. Schwarz and H. Sturm, Ber. 47, 1730 (1914), used a cooling-curve method to compare the heats of fusion of $\text{Li}_2\text{SiO}_3(c)$ and $\text{NaCl}(c)$. From the reported ratio, $\epsilon(\text{Li}_2\text{SiO}_3)/\epsilon(\text{NaCl}) = 0.261/0.402$, where ϵ = heat of fusion in kcal/g, and heat of fusion of $\text{NaCl}(c)$, the value $\Delta H_m^\circ = 6.7$ kcal/mol is derived.

June 30, 1961; Mar. 31, 1964

$\Delta H_f^\circ 0 = -396.8 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -399.3 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 21.930 \pm 0.1 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -399.3 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 2.75 \text{ kcal. mole}^{-1}$
 $\Delta H_m^\circ = 26.33 \text{ kcal. mole}^{-1}$
 $T_m = 1820^\circ\text{K.}$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ was calculated from measurements of solution calorimetry by S. S. Todd and K. K. Kelley, "Heat and Free Energy Data for Tricalcium Dittitanate, Spinel, Lithium Metatitanate and Zinc Titanium Spinel", U. S. Bureau Mines Report Invest. 5193 (1956), according to the following equation:

The $\Delta H_r^\circ 298.15$ value for rutile was obtained from the JANAF Tables and the other $\Delta H_f^\circ 298.15$ values were obtained from "Selected Values of Chemical Thermodynamic Properties" NBS Circular 500 (1952).

Heat Capacity and Entropy.

The low temperature heat capacities were taken from E. G. King, J. Am. Chem. Soc. 77, 2150 (1955). These low temperature heat capacities were fit to the high temperature heat contents from A. U. Christensen, K. C. Conway, and K. K. Kelley, "High Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bur. Mines Rept. Invest. 5565 (1960).

The $S_{298.15}^\circ = 21.9$ was obtained from E. G. King, loc. cit. based on the measured $S_{298.15}^\circ$ and the extrapolated S_{51}° - S_0° .

Transition Data.

A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit. reported that lithium metatitanate undergoes a transition from the α to the β form at $1,485^\circ\text{K.}$ with an absorption of $2.750 \text{ kcal. mole}^{-1}$.

Melting Data.

The T_m and ΔH_m° were obtained from A. U. Christensen, K. C. Conway, and K. K. Kelley, loc. cit.

$S_{298.15}^\circ = 35.355 \text{ cal. mole}^{-1} \text{ deg.}^{-1}$
 $\Delta H_f^\circ 298.15 = -374.374 \text{ kcal. mole}^{-1}$
 $\Delta F_f^\circ 298.15 = -356.667 \text{ kcal. mole}^{-1}$
 $T_m = 1820^\circ\text{K.}$

Heat of Formation.

The $\Delta H_f^\circ 298.15$ was obtained from the heat of formation of the crystal by adding ΔH_m and the difference between $H_{1820}^\circ - H_{298}^\circ$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacities were reported by A. U. Christensen, K. C. Conway, and K. K. Kelley, "High-Temperature Heat Contents and Entropies of Aluminates and Ferrites of Lithium, Sodium, and of Lithium Titanate", U. S. Bureau Mines Report Invest. 5565 (1960). The measured heat capacity is extrapolated to an assumed glass transition temperature of 1214°K. , below which the heat capacity is taken to be equal to that of the crystal.

The $S_{298.15}^\circ$ was obtained in a manner analogous to that of the heat of formation.

Melting Data.

The T_m and ΔH_m were obtained from A. U. Christensen, K. C. Conway and K. K. Kelley, loc. cit.

ΔH_f⁰ = Unknown

ΔH_f^{298.15} = -612.07 ± 1.0 kcal/mol

ΔH_f⁰ = 0.225 kcal/mol

ΔH_m⁰ = [12.86] kcal/mol

T_m = 1307 ± 1°K

S_{298.15} = [30] gibbs/mol

T_t = 1209°K

Heat of Formation

The heats of solution of $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ in 20 per cent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. of the Geophysical Laboratory, No. 1215, 69 (1933). The authors derived two values of ΔHsoln of $\text{Li}_2\text{O}(\text{c})$ from those of $\text{LiCl}(\text{c})$ and $\text{Li}_2\text{SO}_4(\text{c})$, presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate ΔHsoln of $\text{Li}_2\text{O}(\text{c})$ as -58.74 (chloride scheme, originally -59.36) and -59.83 kcal/mol (sulfate scheme, originally -60.86), using recent ΔH_f²⁹⁸ values for $\text{LiCl}(\text{c})$, $\text{Li}_2\text{SO}_4(\text{c})$, $\text{HCl}(\text{aq})$, $\text{H}_2\text{SO}_4(\text{aq})$, and $\text{Li}_2\text{O}(\text{c})$. The corresponding enthalpy changes, ΔH_f²⁹⁸, for the reaction $\text{Li}_2\text{O}(\text{c}) + 2\text{SiO}_2(\text{quartz}) = \text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ are derived as -33.21 and -34.30 kcal/mol. Adopting the weighted average ΔH_f²⁹⁸ = -33.57 kcal/mol with ΔH_f²⁹⁸(Li_2O , c) = -143.1 kcal/mol and ΔH_f²⁹⁸(SiO_2 , quartz) = -217.7 kcal/mol, we obtain ΔH_f²⁹⁸ = -612.07 kcal/mol for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$. This ΔH_f²⁹⁸($\text{Li}_2\text{Si}_2\text{O}_5$, c) value is independent of future changes in ΔH_f²⁹⁸ of $\text{Li}_2\text{O}(\text{c})$ but the values of ΔHsoln and ΔH_f⁰ are not independent.

The heats of solution of $\text{LiOH}(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ in 20 per cent HF(aq) at 80°C were measured by W. E. Hatton, G. C. Sinke, D. L. Hildenbrand, and D. R. Stull, unpublished work, Thermal Laboratory, The Dow Chemical Co., Midland, Michigan, 1959. By use of a reaction scheme similar to that described on the $\text{Li}_2\text{SiO}_3(\text{c})$ table, the enthalpy change at 298°K for the reaction $2\text{LiOH}(\text{c}) + 2\text{SiO}_2(\text{c}) + \text{Li}_2\text{Si}_2\text{O}_5(\text{c}) + \text{H}_2\text{O}(\text{l})$ was calculated to be -13.44 kcal/mol. Incorporating this value with ΔH_f²⁹⁸ = -115.84, -217.7 and -68.315 kcal/mol for $\text{LiOH}(\text{c})$, $\text{SiO}_2(\text{c})$, and $\text{H}_2\text{O}(\text{l})$, respectively, we obtain ΔH_f²⁹⁸($\text{Li}_2\text{Si}_2\text{O}_5$, c) = -612.20 ± 2.0 kcal/mol, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy

Both heat capacities and S₂₉₈ are estimated by comparison with those for $\text{Na}_2\text{Si}_2\text{O}_5(\text{c})$, $\text{Na}_2\text{O}(\text{c})$ and $\text{Li}_2\text{O}(\text{c})$.

Transition Data

The transition temperature, T_t = 1209°K, is taken from F. C. Kracek, J. Am. Chem. Soc. 61, 2863 (1939). The author estimated a heat of transition of 1 to 2 cal/g based on the arrest in the cooling and heating curves. The value of ΔH_t⁰ is calculated assuming the heat of transition at 1209°K is 1.5 cal/g.

Melting Data

Incongruent melting of $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ at 1033° has been reported by F. C. Kracek, J. Phys. Chem. 34, 2641 (1930); J. Am. Chem. Soc. 61, 2863 (1939). The liquidus temperature of 1034° at the composition 19.92 per cent Li_2O and 80.08 per cent SiO_2 , reported by Kracek (1939), is adopted as T_m. The heat of melting is evaluated such that ΔH_m⁰ + ΔH_f²⁹⁸ = 11.43 kcal/mol, where the value 11.43 kcal/mol is the difference between ΔH_f²⁹⁸ for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{l})$. The latter were determined by solution calorimetry by Kracek (see Heat of Formation sections in $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{l})$ tables).

Lithium Disilicate ($\text{Li}_2\text{Si}_2\text{O}_5$)
(Liquid) GFW = 150.047

GFW = 150.047

(LIQUID)

LITHIUM DISILICATE ($\text{Li}_2\text{Si}_2\text{O}_5$)

$\Delta H_f^{298.15} = -600.640 \pm 1.0$ kcal/mol

$\Delta H_m^* = [12.86]$ kcal/mol

$S_{298.15}^* = [38.237]$ gibbs/mol

$T_m = 1307^\circ\text{K}$

Heat of Formation

The heats of solution of LiCl(c) , $\text{Li}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$ in 20 percent hydrofluoric acid at 74.7°C were measured by F. C. Kracek, Ann. Rept. Director of the Geophysical Laboratory, No. 1215, 69 (1953). Following the same procedure as described in $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ table, we derived the enthalpy changes, ΔH_f^{298} , for the reaction $\text{Li}_2\text{O(c)} + 2\text{SiO}_2(\text{quartz}) = \text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$ as -21.78 and -22.87 kcal/mol. Adopting the weighted average $\Delta H_f^{298} = -72.14$ kcal/mol with $\Delta H_f^{298}(\text{Li}_2\text{O, c}) = -143.1$ kcal/mol and $\Delta H_f^{298}(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta H_f^{298} = -600.640$ kcal/mol for $\text{Li}_2\text{Si}_2\text{O}_5(\text{gl})$. This $\Delta H_f^{298}(\text{Li}_2\text{Si}_2\text{O}_5, \text{gl})$ value is independent of future changes in ΔH_f^* of $\text{Li}_2\text{O(c)}$ but the values of ΔH_{soln} and ΔH_m^* are not independent.

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for $\text{Na}_2\text{Si}_2\text{O}_5(\text{c})$, $\text{Na}_2\text{SiO}_3(\text{c})$ and $\text{Li}_2\text{SiO}_3(\text{c})$. A glass transition temperature at 800°K is assumed, i.e. the heat capacities below 800°K are taken from those for $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ and above 800°K are assumed to be constant.

The S_{298}^* value is obtained from $S_{298}^*(\text{c})$ by adding ΔS_m^* and the difference between $S_{1307}^* - S_{298}^*$ for crystal and liquid.

Melting Data

See $\text{Li}_2\text{Si}_2\text{O}_5(\text{c})$ table for details.

ΔH_f⁰ = UnknownΔH_f⁰_{298.15} = -47.2 ± 1.0 kcal/molS_{298.15} = [9 + 2] gibbs/mol

Heat of Formation.

The adopted ΔH_f⁰_{298.15} = -47.2 ± 1.0 kcal/mol was determined calorimetrically by Neumann et al.¹ by heating Li (c) at 600°C under 5 atm N₂ pressure for 1 minute. The ΔH_f⁰_{298.15} = -131.1 kcal/mol of reaction Li₃N(c) + 3 H₂O (l) = 3 LiOH (aq) + NH₃ (aq) was measured by Guntz.² Based on this ΔH_f⁰_{298.15} the heat of formation was calculated to be -47.02 ± 2 kcal/mol which is in very good agreement with that of Neumann et al.¹. Unfortunately the author does not report the amount of water in LiOH (aq) and we assumed 300 H₂O as the best estimate. Heats of formation for NH₃(aq) = [-19.17] kcal/mol and H₂O (l) = [-68.315] kcal/mol were taken from Wagman et al.³. The ΔH_f⁰ of LiOH + 300 H₂O (-121.30 kcal/mol) was derived from the heats of formation and solution of LiOH(c) (see JANAF table) and the heat of dilution selected by Parker.⁴

Heat Capacity and Entropy.

S. Satoh, Sci. Papers Inst. Phys. Chem. Research (Tokyo) **35**, 162 (1939), has measured enthalpies (273-578°K) and derived an equation for the specific heat of Li₃N. The adopted heat capacities were obtained from this equation. Above 773°K the heat capacities were graphically extrapolated. The entropy was estimated from the contribution 3.5 eu per Li given by W. M. Latimer, "Oxidation Potentials," 2nd Edition, Prentice-Hall, Inc., New York, 1952, and a -1.5 eu contribution for N.

At. Wt. = 24.32

$\Delta H_f^\circ 0 = 0$

$\Delta H_f^\circ 298.15 = 0$

$\Delta H_f^\circ 298.15 = 35.28 \pm 0.01 \text{ kcal. mole}^{-1}$

$\Delta H_f^\circ 298.15 = 7.814 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$T_m = 922 \pm 0.5^\circ\text{K}$

$\Delta H_m = 2.14 \text{ kcal. mole}^{-1}$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

The following heat capacity measurements were considered in drawing a smooth curve of C_p with T : P. L. Smith (1.25-4.2°K) Phil. Mag. 46, 744 (1955); J. R. Clement and H. R. Jeffers (3-13°K) Phys. Rev. 105, 1435 (1957); K. Clausius and J. V. Vaughn (11.3-228.4°K) J. Am. Chem. Soc. 52, 4686, (1930); R. S. Craig, C. A. Krier, L. W. Coffey, E. A. Bates, and W. E. Wallace (12-320°K) J. Am. Chem. Soc. 76, 238 (1954); W. Mannchen and K. Bornkessel (190-300°K) Z. Metallkunde 51, 482-5 (1960); H. Seelkamp (291-773°K) Z. anorg. Chem. 195, 345 (1931); and D. R. Stull and R. A. McDonald (700-900°K) J. Am. Chem. Soc. 77, 5293 (1955). The following heat capacity measurements were noted but not used as the data were either not tabulated, or erratic, or inconsistent or would not have altered the C_p curve: D. L. Martin (0.4-1.5°K) Proc. Phys. Soc. (London) 78, 1482-8 (1961); I. Estermann, S. A. Friedberg, and J. E. Goldman (1.6-4.2°K) Phys. Rev. 87, 582 (1952); E. P. Eastman and W. H. Rodenbush (74.9-288.5°K) J. Am. Chem. Soc. 40, 469 (1918); W. G. Saba, K. P. Sterrett, R. S. Craig, and W. R. Wallace (298-543°K) J. Am. Chem. Soc. 79, 3537 (1957); F. M. Jaeger and T. J. Poppema (273-873°K) Rec. Trav. chim. 55, 492 (1936); J. H. Averbey and E. Griffiths (323-899°K) Proc. Phys. Soc. 36, 378 (1926); E. D. Eastman, A. M. Williams and T. F. Young (373-873°K) J. Am. Chem. Soc. 45, 1178 (1926); and P. Schübel (323-773°K) Z. anorg. Chem. 87, 81 (1914). ΔH_m was obtained by numerical integration using the low temperature C_p data cited above.

Melting.

Melting point is from J. L. Houghton and R. J. M. Payne (922 ± 0.5°K) J. Inst. Met. 54, 279 (1934). Also noted but not used were: R. Chadwick (923°K) J. Inst. Met. 39, 285-300 (1928); W. R. D. Jones (920.5°K) J. Inst. Met. 45, 395-419 (1931).

The heat of melting is from D. R. Stull and R. A. McDonald (loc. cit.)

Heat of Sublimation.

Is obtained by third law calculations from the vapor pressure data on the solid by F. F. Coleman and A. E. Egerton, Phil. Trans Roy. Soc. (London) A234, 177-204 (1935) and the value is confirmed by similar use of the vapor pressure data on the liquid by E. Scheil and P. Wolf, Z. Metallkunde 50, 229-33 (1959); A. Wejmarth, Tek. Tid. 72, 33-9, 44-8 (1942); A. Schneider and E. K. Stoll, Z. Elektrochem. 47, 519-26 (1941); E. Baur and R. Brunner, Helv. Chim. Acta, 17, 958-69 (1934); and H. Hartmann and R. Schneider, Z. anorg. Chem. 180, 275-83 (1929). Additional data noted but not used on the vapor pressure as values were not tabulated or they were erratic of the solid are by J. F. Smith and R. L. Smythe, Acta Metallurgica, 1, 261-7 (1959); A. Eucken, Metallwirtschaft, 15, 64-5 (1936); W. Leitzgeb, Metallwirtschaft, 14, 289 (1935); and of the liquid by P. A. Vetter and O. Kubaschewski, Z. Elektrochem. 57, 243 (1953); W. Leitzgeb, Z. anorg. Chem. 202, 312 (1931); C. Zwikker, Physica, 9, 246 (1928); O. Ruff and H. Hartmann, Z. anorg. Chem. 135, 29-45 (1924); and J. Johnston, Ind. Eng. Chem. 9, 876 (1917).

MAGNESIUM (Mg)

(LIQUID)

AT. WT. = 24.32

$$S_{298.15}^o = [0.159] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^o = 2.140 \text{ cal. mole}^{-1}$$

$$\Delta H_v^o = 30.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^o 298.15 = [2.158] \text{ kcal. mole}^{-1}$$

$$T_m = 922 \pm 0.5^\circ \text{K}$$

$$T_b = 1379^\circ \text{K}$$

Heat of Formation.

$\Delta H_f^o 298.15$ (= $\Delta H_m 298.15$) obtained from $\Delta H_m 922$ by adding $H_{922} - H_{298.15}$ for solid and subtracting $H_{922} - H_{298.15}$ for liquid.

Heat Capacity and Entropy.

The heat capacity measurements of D. R. Stull and R. A. McDonald (950-1100°K) J. Am. Chem. Soc. 77, 5293 (1955) were used. Outside of the observed range C_p was extrapolated linearly with temperature. Below T_m the linear extrapolation was continued until the C_p curve for the solid is encountered at 710°K. At lower temperatures the C_p of the crystal is used. $S_{298.15}^o$ was calculated from that of the solid.

Melting.

See crystal for details.

Vaporization.

The normal boiling point was calculated by the third law and $\Delta H_v 298.15$. This compares with 1377°K computed from the general vapor pressure equation for liquid Mg given on p 221 of Gmelins Handbuch der anorganischen Chemie, System-Nummer 27 (1952), and experimentally determined values; 1376 ± 5°K by A. Schneider and U. Esch, Z. Elektrochem 45, 888 (1939); 1380°K by E. Baur and R. Brunner, Helv. Chim. Acta 17, 958 (1934); 1370°K by W. Leitgeb, Z. anorg. Chem. 202, 305 (1931); and 1395°K by Greenwood, Chem. News 104, 31 (1911).

The $\Delta H_v 1378$ is based on the liquid and ideal gas tables.

Heat of Formation.

$\Delta H_f^{298.15} (-\Delta H_s^{298.15})$ is calculated as described on the table for crystal.

Heat Capacity and Entropy.

Thermodynamic functions were calculated using electronic levels and multiplicities from C. E. Moore [Nat]. Bur. Standards Circ. 467, Vol. 1 (1949)]. Higher levels were averaged.

Heat of Formation

We derive the heat of formation at 0°K from the reaction $Mg(g) + Mg^{+}(g) \rightarrow Mg^{+}(g)$ using the JANAF auxiliary value for $Mg(g)$ and an ionization potential of 178.278 kcal/mol from C. E. Moore, U. S. Natl. Bur. Std. Circ. 487, Vol. I, 1949.

Heat Capacity and Entropy

We take the electronic levels and quantum weights from C. E. Moore, loc. cit. $H_0^{\circ} - H_{298}^{\circ} = -1.481$ kcal/mol at 0°K.

Mg⁺

Mar. 31, 1964

Ground State Configuration $[^2\pi]$

$\Delta H_f^0 = [69 \pm 6] \text{ kcal. mole}^{-1}$

$S_{298.15}^0 = [53.713] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H_f^0 298.15 = [69 \pm 6] \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$\frac{E_i, \text{ cm.}^{-1}}{0}$

$\mu_e = [700] \text{ cm.}^{-1}$

$\mu_e^X = [4.8] \text{ cm.}^{-1}$

$B_e = [0.5542] \text{ cm.}^{-1}$

$\alpha_e = [0.0052]$

$r_e = [1.85] \text{ \AA}$

Heat of Formation.

The $\Delta H_f^0 298.15$ for MgN was estimated from bond strengths using MgO and comparison with analogous pairs of compounds such as, PN and PO, and also the bond strengths of C-N and C-O in organic compounds.

Heat Capacity and Entropy.

The r_e value for MgN was estimated from MgO by comparison with similar pairs PO and PN, SiO and SiN, and AlO and AlN. Using Guggenheimer's Relation, Proc. Phys. Soc. (London) 59, 456 (1946), μ for MgO was found to lie between the single and multiple bonding cases. Magnesium nitride was assumed to be similar to MgO and giving $\mu_e^X = 4.8 \text{ cm.}^{-1}$. B_e was calculated from r_e . The α_e value was calculated from B_e , μ_e and μ_e^X .

The samples of (1) and (2) were finely divided magnesia and the other samples were periclase. Periclase is taken to be the standard state. The high temperature heat content data of (6) and (7) were joined by a Shomate plot with the low temperature C_p data of (4). The heat capacity was extrapolated linearly above 1800°K to a value of 14 cal. mole⁻¹ deg.⁻¹ at 3100°K. $S_{298.15}^o = 6.44$ cal. deg.⁻¹ mole⁻¹ is from (4).

Melting Data.

T_m (MgO, c) = 3088 ± 20°K by R. N. McNally, F. I. Peters, and F. H. Ribbe, J. Am. Ceram. Soc. **44**, 491 (1961) was adopted. Their value is 41°K higher than the earlier measurements of C. W. Knoll, J. Wash. Acad. Sci. **3**, 315 (1913). K. K. Kelley, Bur. Mines Bull. 395 (1956) calculated ΔH_m (MgO, c) = 18.5 ± 1.5 kcal./mole from melting point measurements in the MgO - ZnO system.

Sublimation Data.

T_b is the temperature at which the free energy change of the reaction $MgO(c) = MgO(g)$ approaches zero. The difference between ΔH_f^o 298.15 for MgO(c) and MgO(g) is ΔH_g^o 298.15.

MAGNESIUM OXIDE (MgO)

(LIQUID)

MOL. WT. = 40.3114

$\Delta H_f^0 298.15 = [12.033] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_m^0 298.15 = [-126.137] \text{ kcal. mole}^{-1}$
 $\Delta H_m^0 = [18.5 \pm 1.5] \text{ kcal. mole}^{-1}$
 $\Delta H_v^0 = [113.4] \text{ kcal. mole}^{-1}$
 $T_m = 3098^\circ \text{K.}$
 $T_B = [3533]^\circ \text{K.}$

Heat of Formation.

$\Delta H_f^0 298.15(1)$ was calculated from $\Delta H_f^0 298.15(c)$ by adding ΔH_m^0 and the difference between H_m^0 and liquid.

Heat Capacity and Entropy.

A glass transition is assumed at 2066°K. $C_p(1)$ below 2066°K. were assumed to be equal to those of $\text{MgO}(c)$. At and above 2066°K. the heat capacities were assumed to be constant at $7.25 \text{ cal. deg.}^{-1} \text{ g. atom}^{-1}$. The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See MgO(c) table for details.

Vaporization Data.

W. R. Mott, Tran. Am. Electrochem. Soc. 34, 255 (1918) estimated the boiling point at 3873°K. by comparing crater distances of arc energy deposits with reference compounds. $T_B = 3533^\circ \text{K.}$ is the temperature at which the free energy change of the reaction $\text{MgO}(l) = \text{MgO}(g)$ approaches zero. The difference between $\Delta H_f^0 3533$ for $\text{MgO}(g)$ and $\text{MgO}(l)$ is ΔH_v^0 .

Heat of Formation.

There is considerable discordance in the heat of formation results even though results were adjusted to a common 3Σ ground state where necessary. A mean $\Delta H_f^{\circ} 298$ (MgO, g) = 1.0 ± 20 kcal. mole⁻¹ was selected.

R. L. Altman, J. Phys. Chem. 67, 366 (1963) made a Knudsen effusion and oxygen transpiration study of the vaporization of MgO. The predominant vapor species over MgO(c) were shown to be Mg(g) and O₂(g). MgO transpiration results with oxygen at 1 atm yielded a 3rd law heat of sublimation $\Delta H_{sub}^{\circ} 298$ (MgO, g) = 162.3 kcal. mole⁻¹ and $\Delta H_f^{\circ} 298$ (MgO, g) = 18.6 kcal. mole⁻¹.

J. Drowart, G. Exsteen and G. Verhaegen, Trans. Far. Soc. 50, 1920 (1954) used the Knudsen effusion-mass spectrometer technique to determine relative ion intensities and enthalpies for the reaction $MgO(g) + O(g) \rightarrow Mg(g) + O_2(g)$. After adjusting their values for a 3Σ ground state we calculated $\Delta H_f^{\circ} 298$ (MgO, g) = 11.9 kcal. mole⁻¹. Similar calculations for their data on $MgO(g) + WO_2(g) \rightarrow Mg(g) + WO_3(g)$ yielded $\Delta H_f^{\circ} 298$ = 10.5 kcal. mole⁻¹. The agreement is fortuitous, however, since uncertainties in the JANAF values for $WO_2(g)$ and $WO_3(g)$ are on the order of 7 kcal. each.

R. F. Porter, W. A. Chupka and M. O. Inghram, J. Chem. Phys. 23, 1347 (1955) mass spectrometrically determined an upper limit for the vapor pressure of MgO(g) over MgO(c) at 1950°K. Their results reduce to a lower limit of 148.6 kcal. mole⁻¹ for $\Delta H_f^{\circ} 298.15$ (MgO, c) or a lower limit of 4.9 kcal. mole⁻¹ for $\Delta H_f^{\circ} 298$ (MgO, g).

E. Bulewicz and T. Sugden, Trans. Far. Soc. 55, 720 (1959), using a flame photometric technique, reported $D_0^{\circ} = 98 \pm 2$ kcal. mole⁻¹ for MgO. $\Delta H_f^{\circ} 298$ (MgO, g) = -4.1 kcal. mole⁻¹ was calculated.

I. Veita and K. Gurvich, Optika and Spektroskopiya 2, 22 (1956) used a flame technique to obtain $D_0^{\circ} = 100$ kcal. mole⁻¹. A 4 kcal. mole⁻¹ adjustment for 1Σ to 3Σ yields $\Delta H_f^{\circ} 298$ (MgO, g) = -2.1 kcal. mole⁻¹.

The flame method data of L. Huldt and A. Lagerquist, Arkiv Fysik 2, 335 (1950) yielded a 3Σ adjusted $D_0^{\circ} = 115$ kcal. mole⁻¹. $\Delta H_f^{\circ} 298$ (MgO, g) = -21.1 kcal. mole⁻¹ was calculated.

L. Brewer and R. F. Porter, J. Chem. Phys. 22, 1876 (1954) have shown by vapor pressure measurements on MgO(c) that the solid vaporizes mainly into molecular species. They gave spectroscopic evidence that the 3Σ electronic state of MgO(g) is not the principal vaporizing species. Using their vapor pressures for the reaction $MgO(c) = MgO(g)$ and a 3Σ ground state we calculated 2nd and 3rd law heat of sublimation at 298°K. of 120.0 and 129.1 kcal. mole⁻¹. The 3rd law value yields $\Delta H_f^{\circ} 298$ (MgO, g) = -14.6 kcal. mole⁻¹.

Heat Capacity and Entropy.

The fundamental frequency and anharmonicity correction were reported by L. Brewer and R. Porter, J. Chem. Phys. 22, 1876 (1954) and are based on a 3Σ ground state. The rotational constants were estimated by H. L. Schick 35 al. AVCO Corp. RAD-SR-82-251, 15 Dec. 1962. Although the ground state and spectroscopic constants are in doubt, the free energies are probably within RT in 3 of true values.

Heat of Formation

Torgeson et al. (1) report a $\Delta H_{298}^\circ = -8.69 \pm 0.15$ kcal/mol for reaction (a). They used a hydrofluoric acid solution calorimeter and measured the heats of solution of each component. They appear to have made the water-absorption correction to the heat of solution of SiO₂(c) in the wrong direction. We reverse the correction so that the new ΔH_{298}° almost overlaps the range observed by King (11). We derive ΔH_{298}° (MgSiO₃, c) = -370.20 ± 1.0 kcal/mol using the ΔH_{298}° of MgO(c) and SiO₂ (c, low quartz) from the JANAF tables.

Reesman et al. (2) calculated a $\Delta G_{298}^\circ = 23.72$ kcal/mol for reaction (b) using aqueous solubility data. We use the ΔG_{298}° of H₂O(l) and OH⁻(aq) from source 3, ΔG_{298}° of H₄SiO₄(aq) from source 4 and ΔG_{298}° of Mg⁺⁺(aq) from source 5 and we obtain a ΔG_{298}° (MgSiO₃, c) = -332.534 kcal/mol. We derive a ΔH_{298}° (MgSiO₃, c) = -373.253 kcal/mol using the above ΔG_{298}° of MgSiO₃(c) and the entropies of Mg(c), Si(c) and O₂(g) from the JANAF tables.

We choose the heat of formation derived from the Torgeson et al. (1) which is considered to be better since it relates directly to the oxides. Also the ΔG_{298}° (MgSiO₃, c) thus calculated is in very good agreement with that derived from the activities of SiO₂ and MgO (in the SiO₂-MgO system) measured by Rein et al. (9). The ΔH_{298}° (MgSiO₃, c) derived from the work of Reesman et al. is less accurate and involves uncertainties in the auxiliary data used to calculate the value.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53 - 295°K) of Kelley (2). Wagner (9) measured the average heat capacities in the temperature range 580 - 1570°K. Using his data we derive the high temperature heat capacities which are joined smoothly with the low temperature values by a constrained fitting technique. The Cp values at 903 - 1258°K and above 1258°K are derived as 28.762 and 29.262 gibbs/mol, respectively, by assuming that the data of Wagner (9) pertain to the stable phase in these regions. The entropy is based on S°₀ = 0.49 eu.

Transition Data

T₁ = 903°K is obtained from Boyd et al. (9). The authors determined the phase diagram boundary at high pressures and extrapolated to one atmosphere. T₂ = 1258°K is taken from Atlas (10). Below 903°K the phase is known as clinonastatite. Between 903° and 1258°K it is rhombic enstatite and above 1258°K it is protonastatite. We calculate ΔH_{298}° and ΔH_{298}° from dT/dP (slopes of the isotherms) = 2.6°/kbar and 84°/kbar reported by Boyd et al. (9, 11) and from the densities of clinonastatite (3.210 gm/cc) and rhombic enstatite (3.208 gm/cc) reported by Stephenson et al. (11) and the density of protonastatite (3.10 gm/cc) reported by Smith (12).

MAGNESIUM METASILICATE (MgSiO_3) (LIQUID)

S°_{298.15} = 122.112 J/gibbs/mol

T₁ = 903 °K

T₂ = 1258 °K

T_m = 1850 ± 2 °K

Heat of Formation

The heat of formation is obtained from ΔHf°₂₉₈(c) by adding ΔHm° and the difference between H°_m - H°₂₉₈ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 900°K. Below 900°K the heat capacity is obtained from the heat capacity of the crystal.

Above 900°K the heat capacity is assumed constant and estimated as 35 gibbs/mol or 7 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

See crystal table.

Melting Data

T_m is taken from M. L. Bowen and O. Andersen, Am. J. Sci. 27, 487 (1914). MgSiO_3 (c) melts incongruently in the temperature range 1830 - 1850°K at atmospheric pressure. ΔHm° is estimated from the phase diagrams of the MgSiO_3 - TiO_2 system reported by

I. D. MacGregor, Ann. Rept. Director of the Geophysical Laboratory, No. 1455, 135-9 (1965). The phase diagrams were determined at 10 and 20 kbars pressure where MgSiO_3 (c) melts congruently.

MgO_3Si

GFW = 100.3962

ΔHf°_{298.15} = [-357.281 ± 5] kcal/mol

ΔHf°₁ = 0.16 kcal/mol

ΔHf°₂ = 0.39 kcal/mol

ΔHm° = [18 ± 5] kcal/mol

$$\Delta H_f^\circ = -373.63 \pm 1.5 \text{ kcal/mol}$$

$$\Delta H_f^\circ = -375.85 \pm 1.5 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [21.6] \text{ kcal/mol}$$

$$S_{298.15}^\circ = 17.82 \pm 0.1 \text{ gibbs/mol}$$

$$T_m = 1953 \pm 20^\circ \text{K}$$

Heat of Formation

The adopted heat of formation is calculated from $\Delta H_f^\circ = -6.35 \pm 0.25 \text{ kcal/mol}$ for the reaction

$\text{MgO(c)} + \text{TiO}_2(\text{rutile}) + \text{MgTiO}_3(\text{c})$ measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. For the same reaction a value of $\Delta H_f^\circ = -5.5 \pm 0.1 \text{ kcal/mol}$ was obtained with a calorimetric bomb method by B. I. Ronfilov and N. N. Feodos'ev, Russ. J. Inorg. Chem. (English Transl.) 3, 1452 (1964). These authors used the oxidation of lampblack in order to initiate the formation of the titanate from the oxides. Unfortunately the desired heat of reaction was only 1.2 to 1.5 percent of the total measured heat, and consequently this result appears to be more uncertain than that measured by the solution calorimetric method.

Heat Capacity and Entropy

Low temperature heat capacities are from the data ($52 - 298^\circ \text{K}$) of C. H. Shonate, J. Am. Chem. Soc. 67, 964 (1946). High temperature enthalpies have been measured ($402 - 1720^\circ \text{K}$) by B. F. Naylor and O. A. Cook, J. Am. Chem. Soc. 68, 1003 (1946). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S_2^\circ = 0.45 \text{ eu}$.

Melting Data

See liquid table.

GFW = 120.2102

(LIQUID)

MAGNESIUM METATITANATE (MgTiO₃)

$$\Delta H_f^{298.15} = [-357.842 \pm 1.5] \text{ kcal/mol}$$

$$\Delta H_m^* = [21.6] \text{ kcal/mol}$$

$$S_{298.15}^* = [26.549] \text{ gibbs/mol}$$

$$T_m = 1953 \pm 20^\circ\text{K}$$

Heat of Formation

ΔH_f^{298} is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^* and the difference between H_{298}^* and H_{298} for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. The heat capacity below 1300°K is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 39 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting point at 1903°K. The ΔH_m^* is estimated from those of Na₂O·2TiO₂ and Na₂O·TiO₂ observed by Naylor (3) and CaO·TiO₂·SiO₂ observed by King (4).

$\Delta H_f^0 = -298.8 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 \text{ 298.15} = -301.6 \pm 5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 3.5 \text{ kcal. mole}^{-1}$

$S_{298.15}^0 = 21.844 \pm 0.2 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1400^\circ \text{K.}$

Heat of Formation.

The adopted $\Delta H_f^0 \text{ 298.15} = -301.6 \pm 5 \text{ kcal. mole}^{-1}$ was calculated from the $\Delta H_f^0 \text{ 298.15} = 63.3 \pm 5 \text{ kcal. mole}^{-1}$ for the reaction $\text{MgO(c)} + \text{SO}_3(\text{g}) = \text{MgSO}_4(\text{c})$. The value of $\Delta H_f^0 \text{ 298.15}$ was calculated by the third law method using the equilibrium data obtained from a transpiration study by Knopf and Staude.¹ In addition Marchal² measured the total pressure of $\text{SO}_3(\text{g})$, $\text{SO}_2(\text{g})$ and $\text{O}_2(\text{g})$ above $\text{MgSO}_4(\text{c})$ and partial pressures were obtained by application of the $\text{SO}_2\text{-SO}_3$ equilibrium data. Another value of $\Delta H_f^0 \text{ 298.15}$ (MgSO_4 , c) may be derived from the measured heat of solution of $\text{MgSO}_4(\text{c})$ by Thomsen^{3a} and the measured heats of mixing of $\text{MgCl}_2(200 \text{ H}_2\text{O})$ with $\text{H}_2\text{SO}_4(200 \text{ H}_2\text{O})$ and $\text{MgSO}_4(200 \text{ H}_2\text{O})$ with $2\text{HCl}(100 \text{ H}_2\text{O})$ by Thomsen^{3b}.

Heat Capacity and Entropy.

The low temperature heat capacities $53.3\text{-}295.4^\circ \text{K.}$ were measured by G. E. Moore and K. K. Kelley, J. Am. Chem. Soc. **64**, 2949 (1942). The heat capacities in the temperature range $298\text{-}1400^\circ \text{K.}$ were estimated from the equation $\text{MgSO}_4(\text{c}) = \text{CaSO}_4(\text{c}) + \text{MgO(c)} - \text{CaO(c)}$. $\text{CaSO}_4(\text{c})$ and CaO(c) C_p were calculated using the equations $C_p = 16.78 + 23.60 \times 10^{-3} T$ and $C_p = 11.67 + 1.08 \times 10^{-3} T - 1.56 \times 10^{-6} T^2$ respectively, K. K. Kelley, U. S. Bur. Mines Bull. **584** (1960). The heat capacity of MgO(c) was calculated from the correlation of the low temperature heat capacities and high temperature heat content using the Shomate functions to back calculate the heat capacities. The values from the two sources join smoothly at 298°K. Above the melting point (1400°K.) the heat capacity was graphically extrapolated. The entropy was calculated at 50.12°K. using the Debye and Einstein function $D(\frac{298}{50.12}) + 2E(\frac{298}{50.12}) + E(\frac{298}{50.12})$ given by G. E. Moore and K. K. Kelley loc. cit. The value of $S_{50.12}^0 = 1.08 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

MAGNESIUM SULFATE (MgSO₄) (LIQUID)

MOL. WT. = 120.3736

ΔH_f^o 298.15 = -297.9 ± 5 kcal. mole⁻¹

ΔH_m^o = 3.5 kcal. mole⁻¹

S_{298.15}^o = 24.464 ± 0.2 cal. deg.⁻¹ mole⁻¹

T_m = 1400°K.

Heat of Formation.

The ΔH_f^o 298.15 was obtained from ΔH_f^o 298.15(c) by adding ΔH_m^o and the difference between H_m^o - H_{298.15}^o for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 1000°K. The heat capacity below 1000°K. was obtained from the heat capacity of the crystal. Above 1000°K. the heat capacity was assumed constant and estimated as 38.0 cal. deg.⁻¹ mole⁻¹ by comparison with those for MgCl₂(l), KCl(l) and K₂SO₄(l). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See MgSO₄(c) table.

MgO₄S

MAGNESIUM TUNGSTATE (MgWO₄)

(CRYSTAL)

GFW = 272.1596

$\Delta H_f^\circ = -359.9 \pm 8$ kcal/mol
 $\Delta H_f^\circ = -382.3 \pm 8$ kcal/mol
 $\Delta H_f^\circ = \text{Unknown}$

$S_{298.15}^\circ = 24.18 \pm 0.2$ gibbs/mol
 $T_m = \text{Unknown}$

Heat of Formation.

T. N. Rezukhina and V. A. Levitskii¹ measured the emf, $E = 0.2453 - 0.001264T$, for the cell reaction $\text{MgO}(c) + \text{W}(c) + 3\text{FeO}_{0.95}\text{O}(c) \rightarrow \text{MgWO}_4(c) + 2.85 \text{Fe}(c)$, in the temperature range $1220^\circ - 1370^\circ \text{K}$. Incorporating the results with auxiliary thermal data, the authors obtained $\Delta H_f^\circ = -224,370 + 65.67T$ (cal/mol) for $\text{MgO}(c) + \text{W}(c) + 3/2\text{O}_2(g) \rightarrow \text{MgWO}_4(c)$. Third law analysis of the ΔH_f° equation gives $\Delta H_f^\circ = -218.6$ kcal/mol, from which the adopted $\Delta H_f^\circ(298 \text{ MgWO}_4, c)$, -362.3 kcal/mol, is calculated. The second law analysis gives $\Delta H_f^\circ(298 \text{ MgWO}_4, c) = -372.7$ kcal/mol. The drift in the third law analysis is 8.0 eu.

T. N. Rezukhina, Ya. I. Gerasimov and Yu. P. Simanov² determined the Gibbs energy changes $\Delta G_r^\circ = 51,300 - 27.67T$ (cal/mol) for the reaction $\text{MgWO}_4(c) + 3\text{H}_2(g) \rightarrow \text{MgO}(c) + \text{W}(c) + 3\text{H}_2\text{O}(g)$ in the temperature range $1073^\circ \text{K} - 1273^\circ \text{K}$ by a circulation method. This leads to heats of formation of -366.1 kcal/mol by the third law method and -377.2 kcal/mol by the second law method. Both determinations were performed by Rezukhina and his co-workers, but they considered the data obtained by the emf method to be more reliable than that derived from heterogeneous equilibria.

Heat Capacity and Entropy.

Low temperature heat capacities, $52.92^\circ - 296.09^\circ \text{K}$, were measured calorimetrically by E. G. King and W. W. Weller³. The heat capacities above 300°K are estimated by comparison with those of $\text{CaWO}_4(c)$ ⁴, $\text{CaO}(c)$ ⁵, and $\text{MgO}(c)$ ⁶. These two sets of data are joined smoothly at 298°K by a graphical method.

The entropy, $S_{298}^\circ = 21.184$ eu, is taken from King and Weller³, based on an extrapolation of $S_{517}^\circ = 1.27$ eu. No spin-magnetic entropy is predicted below 51°K based on the diamagnetism observed by Ya. I. Gerasimov⁷.

MAGNESIUM DITITANATE (MgTi₂O₅) (CRYSTAL)

GFW = 200.109

$$\Delta H_f^\circ = -596.43 \pm 2.5 \text{ kcal/mol}$$

$$\Delta H_f^\circ = -599.75 \pm 2.5 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [35] \text{ kcal/mol}$$

$$S_{298.15}^\circ = 32.41 \pm 1.5 \text{ gibbs/mol}$$

$$T_m = 1963 \pm 20^\circ\text{K}$$

Heat of Formation

ΔH_f° is calculated from $\Delta H_{298}^\circ = -4.45 \pm 0.45 \text{ kcal/mol}$ for the reaction $\text{MgO}(c) + 2\text{TiO}_2(\text{rutile}) = \text{MgTi}_2\text{O}_5(c)$ measured by K. K. Kelley, S. S. Todd and E. G. King, U. S. Bur. Mines RI 5059, 1954, using a solution calorimetric method. The uncertainty of $\pm 2.5 \text{ kcal/mol}$ assigned to the heat of formation is due primarily to $\text{TiO}_2(\text{rutile})$.

Heat Capacity and Entropy

Low temperature heat capacities are from the data ($52 - 298^\circ\text{K}$) of S. S. Todd, J. Am. Chem. Soc. **74**, 4689 (1952). High temperature enthalpies have been measured ($397 - 1812^\circ\text{K}$) by R. L. Orr and J. P. Coughlin, J. Am. Chem. Soc. **74**, 3186 (1952). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on $S_{51}^\circ - S_0^\circ = 1.11 \text{ eu}$.

Kelley et al., loc. cit., suggested that there may be a zero-point entropy due to randomness of the cations. The authors estimated S_0° from the following alternative assumptions: (a) all the Mg and Ti ions are randomly distributed among the lattice sites giving 3.79 eu and (b) all the Mg and one-half of the Ti ions are randomly distributed giving 2.75 eu . These assumptions were proposed in order to make MgTi_2O_5 stable relative to MgTiO_3 at high temperatures. Phase data of F. Massazza and E. Sirchia, 16th Int. Congress of Pure and Appl. Chem., Inorg. Sect., Paris (1957), pp. 161-8, Butterworths Scientific Publications, London, 1958, indicate that MgTi_2O_5 melts congruently at $1963 \pm 20^\circ\text{K}$ and that there is a eutectic with MgTiO_3 at $1873 \pm 20^\circ\text{K}$. These data require that $\Delta G^\circ < 0$ for $\text{MgTiO}_3(c) + \text{TiO}_2(\text{rutile}) \rightarrow \text{MgTi}_2\text{O}_5(c)$ in this temperature range. To make $\Delta G^\circ < 0$ would require that $S_{298.15}^\circ > 32.035 \text{ eu}$. We adopt a compromise zero-point entropy of 2 eu between the upper (3.79 eu) and the lower (0.35 eu) limits.

June 30, 1961; June 30, 1967

MAGNESIUM DITITANATE (MgTi₂O₅)

(LIQUID)

GFw = 200.109

S_{298.15} = [47.27] gibbs/mol

ΔH^c_{298.15} = [-569.385 ± 2] kcal/mol

ΔH^m = [35] kcal/mol

T_m = 1963 ± 20°K

Heat of Formation

The heat of formation is obtained from ΔH^c₂₉₈(c) by adding ΔH^m and the difference between H^c₂₉₈ and H^c₂₉₈ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1300°K. Below 1300°K the heat capacity is obtained from the heat capacity of the crystal. Above 1300°K the heat capacity is assumed constant and estimated as 62/4 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The congruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) indicates congruent melting at 1925°K. The ΔH^m is estimated from those of Na₂O·2TiO₂ and Na₂O·TiO₂ observed by Naylor (3) and CaO·TiO₂·SiO₂ observed by King (4).

MAGNESIUM ORTHOSILICATE (Mg₂SiO₄)

(CRYSTAL)

GFW = 140.7076

ΔH_f⁰ = -517.12 ± 1.0 kcal/mol

ΔH_f^{298.15} = -520.30 ± 1.0 kcal/mol

ΔH_m⁰ = [17 ± 5] kcal/mol

Heat of Formation

Torgeson et al. (1) have reported a ΔH_f²⁹⁸ = -15.1 ± 0.2 kcal/mol for reaction (a). They used an HF solution calorimeter and measured the heats of solution of each component. We derive ΔH_f²⁹⁸(Mg₂SiO₄, c) = -520.30 ± 1.0 kcal/mol using the ΔH_f²⁹⁸ of MgO(c) and SiO₂(c, low quartz) from JANAF tables.

Kapustinikii et al. (2) used the same method but measured only ΔH_f²⁹⁸ = 95.00 ± 0.47 kcal/mol for reaction (b). We calculate ΔH_f²⁹⁸(Mg₂SiO₄, c) = -522.27 kcal/mol using the ΔH_f²⁹⁸ of H₂SiF₆(aq) from source 3 and the ΔH_f²⁹⁸ of H₂O(l) and HF(aq) from source 4.

Reesman et al. (3) calculated a ΔG_f²⁹⁸ = 42.46 kcal/mol for reaction (c) using aqueous solubility data. We use the ΔG_f²⁹⁸ of H₂O(l) and OH⁻(aq) from source 4, ΔG_f²⁹⁸ of H₂SiO₄(aq) from source 3 and ΔG_f²⁹⁸ of Mg²⁺(aq) from source 6 and we obtain a ΔG_f²⁹⁸(Mg₂SiO₄, c) = -498.784 kcal/mol. We derive a ΔH_f²⁹⁸(Mg₂SiO₄, c) = -524.848 kcal/mol using the above ΔG_f²⁹⁸ of Mg₂SiO₄(c) and the entropies of Mg(c), Si(c) and O₂(g) from the JANAF tables.

The adopted value is from the work of Torgeson et al. (1) which is considered to be the most reliable since it relates directly to the oxides. The other reported values are less accurate and involve uncertainties in the auxiliary data used to derive the heat of formation.

Source	Method	Reaction	ΔH _f ²⁹⁸ kcal/mol	ΔG _f ²⁹⁸ kcal/mol
Torgeson et al.	Hydrofluoric acid solution calorimeter	(a) 2MgO(c) + SiO ₂ (c) = Mg ₂ SiO ₄ (c)	-15.10 ± 0.2	-520.3
Kapustinikii et al.	Hydrofluoric acid solution calorimeter	(b) Mg ₂ SiO ₄ (c) + 10HF(4.44H ₂ O) = 2MgF ₂ (c) + H ₂ SiF ₆ (714HF·3220H ₂ O) + 4H ₂ O(l)	95.0 ± 0.47	-522.27

Heat Capacity and Entropy

Low temperature heat capacities are from the data (53-235°K) of Kelley (7). High temperature enthalpies have been measured (398-1808°K) by Orr (8). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. The entropy is based on S₀⁰ = 0.60 eu.

Melting Data

T_m is obtained from Davis et al. (9). ΔH_m⁰ is estimated from MacGregor's (10) phase diagrams of the Mg₂SiO₄ - TiO₂ system. The phase diagrams were determined at 10 and 20 kbars pressure.

Magnesium Orthosilicate (Mg_2SiO_4)

(Liquid) GFW = 140.7076

GFW = 140.7076

(LIQUID)

MAGNESIUM ORTHOSILICATE (Mg_2SiO_4)

$\Delta H_f^{298.15} = [-505.229 \pm 5] \text{ kcal/mol}$

$\Delta H_m^* = [17 \pm 5] \text{ kcal/mol}$

$S_{298.15}^* = [29.407] \text{ gibbs/mol}$

$T_m = 2171 \pm 11^\circ K$

Heat of Formation

The heat of formation is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^* and the difference between H_{lm}^* and H_{298}^* for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at $1400^\circ K$. Below $1400^\circ K$ the heat capacity is obtained from the heat capacity of the crystal. Above $1400^\circ K$ the heat capacity is assumed constant and estimated as 49 gibbs/mol or 7 gibbs/g-atom . The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See crystal table.

MAGNESIUM ORTHOTITANATE (Mg_2TiO_4) (CRYSTAL)

GFW = 160.5216

$$\Delta H_f^\circ = -514.11 \pm 1.5 \text{ kcal/mol}$$

$$\Delta H_f^\circ_{298.15} = -517.3 \pm 1.5 \text{ kcal/mol}$$

$$\Delta H_m^\circ = [31] \text{ kcal/mol}$$

$$S^\circ_{298.15} = 27.51 \pm 1.5 \text{ gibbs/mol}$$

$$T_m = 2013 \pm 20^\circ \text{K}$$

Heat of Formation

The heat of formation is calculated from $\Delta H^\circ_{298} = -4.1 \pm 0.25 \text{ kcal/mol}$ for the reaction $2 \text{ MgO(c)} + \text{TiO}_2(\text{rutile}) \rightarrow \text{Mg}_2\text{TiO}_4(\text{c})$ measured by Kelley (1), using a solution calorimetric method. The uncertainty of $\pm 1.5 \text{ kcal/mol}$ assigned to the heat of formation is due primarily to $\text{TiO}_2(\text{rutile})$.

Heat Capacity and Entropy

Low temperature heat capacities are from the data ($52 - 298^\circ \text{K}$) of Todd (2).

High temperature enthalpies have been measured ($392 - 1817^\circ \text{K}$) by Orr (3). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values.

The entropy is based on $S^\circ_0 = 0.66 + 2.75 = 3.41 \text{ eu}$, where the first term is a lattice contribution and the second term is a zero-point entropy of $2R \ln 2$ corresponding to random distribution of Ti and Mg on the octahedral sites of the spinel lattice. The adopted value is $S^\circ_{298} = 27.51 \pm 1.5 \text{ eu}$ instead of $24.76 \pm 0.15 \text{ eu}$ as given by Todd.

Barth (4) showed from intensities of the X-ray diffraction lines that Mg_2TiO_4 is a spinel of the inverse (or variate) class. Thus, half of the Mg ions occupy the tetrahedral interstices in the oxygen lattice, while the remaining Mg ions and the Ti ions are (presumably) randomly located in the octahedral interstices. This conclusion was confirmed by Romeijn (5).

King and Kelley (6) suggested that the degree of structural randomness is not established and that it may vary with the sample of Mg_2TiO_4 ; thus, they recommended an intermediate value of $R \ln 2$ for the zero-point entropy. In a previous review, however, Kelley (1) used the theoretical value of $2R \ln 2$ in order to make Mg_2TiO_4 stable relative to MgTiO_3 at high temperatures. We choose to adopt $2R \ln 2$, although the evidence is not conclusive. Recent studies of solid state reactions by Bartsch and Werner (7) indicate that ΔG° is negative for $\text{MgTiO}_3(\text{c}) + \text{MgO(c)} \rightarrow \text{Mg}_2\text{TiO}_4(\text{c})$ at temperatures of 1673°K and above. Both $R \ln 2$ and $2R \ln 2$ are consistent with this evidence.

Melting Data

See liquid table.

Heat of Formation

ΔH_f° is obtained from $\Delta H_f^\circ(298.15^\circ K)$ by adding ΔH_m° and the difference between H_m° and H_{298}° for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 1400°K. Below 1400°K the heat capacity is obtained from the heat capacity of the crystal. Above 1400°K the heat capacity is assumed constant and estimated as 54.6 gibbs/mol or 7.8 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The incongruent melting point is obtained from Massazza (1). Previous work by Coughanour (2) suggested congruent melting at 2005°K. The ΔH_m° is estimated from those of $Na_2O \cdot 2TiO_2$ and $Na_2O \cdot TiO_2$ observed by Naylor (3) and $CaO \cdot TiO_2 \cdot SiO_2$ observed by King (4).

DIMAGNESIUM SILICIDE (Mg_2Si) (crystal)

Mol. Wt. = 76.73

ΔH_f^0 298.15 = -18.6 kcal. mole⁻¹

$S_{298.15}^0$ = [19.5] cal. deg.⁻¹ mole⁻¹

T_m = 1375°K

ΔH_m = [15.33] kcal. mole⁻¹

Heat of Formation. ΔH_f^0 298.15 was found in the National Bureau of Standards Circular 500 (1952).

Heat Capacity and Entropy. C_p taken from Kubaschewski and Evans, "Metallurgical Thermochemistry," 3rd Edition, Pergamon Press Ltd., New York, (1958). $S_{298.15}$ was estimated.

Melting Data. T_m was taken from NBS Circular 500 (1952). ΔH_m was found in Wilson, Beahm, and Cooper, "Determination and Analysis of the Potentials of Thermal Energy Storage Materials," Gallery Chemical Co., Gallery, Pa., June 30, 1961.

DIMAGNESIUM SILICIDE (Mg₂Si)

(Liquid)

Mol. Wt. = 76.73

ΔH°_f 298.15 = -3.749 kcal. mole⁻¹S°_{298.15} = [30.2] cal. deg.⁻¹ mole⁻¹T_m = 1375°KΔH_m = [15.33] kcal. mole⁻¹Heat of Formation. ΔH°_f 298.15 was based on ΔH°_f 298.15 of the crystal and the heat of melting.Heat Capacity and Entropy. C_p was estimated. A glass transition was assumed at 916°K. S°_{298.15} was calculated from the entropy of the crystal and the entropy of melting.

Trimagnesium Dinitride (Mg_3N_2)
(Solid) Mol. Wt. = 100.98

Dec. 31, 1960; Mar. 31, 1963

MAGNESIUM ORTHOPHOSPHATE ($\text{Mg}_3\text{P}_2\text{O}_8$)

(CRYSTAL)

MOL. WT. = 262.91

ΔH_f⁰ = Unknown

ΔH_f⁰ 298.15 = -895.1 ± 2.5 kcal. mole⁻¹

ΔH_m⁰ = [29 ± 10] kcal. mole⁻¹

S_{298.15}⁰ = [45] cal. deg. ⁻¹ mole⁻¹

T_m = 1621°K.

Heat of Formation.

The selected ΔH_f⁰ 298.15 is a weighted average of a revised calorimetric determination and a third law calculation using equilibrium data.

A calorimetric determination of the heat of formation reported by C. G. Stevens and E. T. Turkdogan, Trans. Faraday Soc. 50, 370 (1954) was revised three ways:

1. The heat of reaction for the reaction $3\text{MgO}(c) + \text{P}_2\text{O}_5(\text{orthorhombic}) \rightarrow \text{Mg}_3\text{P}_2\text{O}_8(c)$ had been evaluated at 348°K. A small temperature correction to 298.15 was made with thermal data not available to Stevens and Turkdogan (loc. cit.) on MgO (W. F. Glauque, J. Am. Chem. Soc. 71, 5192 (1949)), P_2O_5 (JANAP Table, Dec. 31, 1962) and $\text{Mg}_3\text{P}_2\text{O}_8$ (this table).

2. A new ΔH_f⁰ 298.15 for $\text{P}_2\text{O}_5(\text{hexagonal})$ as reported by W. S. Holmes, Trans. Faraday Soc. 58, 1916 (1962) was combined with the heat of reaction, -6.85 ± 1.0 kcal. mole⁻¹, for the reaction: $\text{P}_2\text{O}_5(\text{hexagonal}) \rightarrow \text{P}_2\text{O}_5(\text{orthorhombic})$ as reported by W. L. Hill, G. T. Faust, and S. B. Hendricks, J. Am. Chem. Soc. 65, 734 (1943).

3. A correction of +0.35 kcal. mole⁻¹ was made for the change in phosphorus reference state from white (α) to red (V). (The correction is +0.35 kcal./mole of $\text{Mg}_3\text{P}_2\text{O}_8$ or +4.173 kcal. mole⁻¹ of P.)

This revised ΔH_f⁰ 298.15, -897.60 ± 2.0 kcal. mole⁻¹, would appear to be more reliable than the original value reported by Stevens and Turkdogan (loc. cit.).

For the reaction

the third law treatment of the equilibrium data of J. B. Bookey, J. Iron Steel Institute (London) 172, 68 (1952) and the JANAP Table free energy functions gave a ΔH_f⁰ 298.15 = -893.11 kcal. mole⁻¹.

The quantity, -895.10 ± 2.50 kcal. mole⁻¹, is taken as the most probable value for the heat of formation of magnesium orthophosphate.

Heat Capacity and Entropy.

The entropy at 298.15 was estimated by considering the additive entropy constants of K. K. Kelley, private communication, June 1960, and E. L. Evans and O. Kubaschewski, "Metallurgical Thermochemistry, 1958. The heat capacity was estimated in a similar manner by considering the heat capacities of the constituent elements and related compounds such as Mg, O₂, MgO, P, P₂O₅, Ca₃P₂O₇, and Ca₃P₂O₈.

Melting Data.

The melting point, 1621°K, as reported by Stevens and Turkdogan (loc. cit.) was selected. There is disagreement on the melting point in the literature. From the work of H. Winter, Diss. Universitäts zu Leipzig 1913, K. K. Kelley, U. S. Bureau of Mines Bulletin 393, (1956) has quoted a melting point of 1457°K and has calculated a "rather uncertain value" of 11,300 kcal./mole for the heat of fusion. J. B. Bookey (loc. cit.) has found a melting point of 1703°K. J. Berak, Roczniki Chm. 32, 17 (1955) gives 1630°K as the melting point.

Magnesium Orthophosphate ($Mg_3P_2O_8$)

(Liquid) Mol. Wt. = 262.91

MOL. WT. = 262.91

Dec. 31, 1960; Mar. 31, 1963

Heat of Formation.
The ΔH_f^o 298.15 was calculated from the estimated ΔH_m and the ΔH_f^o 298.15 of the crystal.

Heat Capacity and Entropy.

The heat capacity was estimated as 13/11 of the corresponding heat capacity of $Ca_3P_2O_8$, as given in K. K. Kelley.

Kelley, U. S. Bur. Mines Bull. 5841 (1960).

Melting Data.

The heat of melting was estimated by taking 13/11 of the ΔH_m of $Ca_3P_2O_8$, as given in K. K. Kelley (loc. cit.)

$\Delta H_{298}^{\circ} = 157.3 \pm 0.5$ kcal/mol

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Below 20°K several investigators 1,2,3,4,5,6 have determined the heat capacity, and an average of these determinations was used to obtain a Debye theta = 440 and an electronic gamma = 4.7×10^{-4} gibbs/mol-deg. From these the entropy at 20°K was calculated as 0.024 gibbs/mol and the enthalpy as 0.265 cal. Between 20°K and 271°K the data of Clusius and Franzosini⁷ are the adopted heat capacities. The data of Simon and Zeidler⁸ are as much as 2.5% high below 78°K and as much as 1% low above this.

Both the high temperature enthalpies and heat capacity have been measured by several investigators and there is generally good agreement in the 1000-2000°K range. A smooth curve was drawn through the high temperature enthalpy data of several investigators 7,8,9,10,11,12 which was also joined smoothly to the integrated low temperature data of Clusius and Franzosini. The heat capacity was obtained by fitting the smoothed enthalpy data with a polynomial and differentiating. The heat capacity obtained agreed satisfactorily with that reported in several investigations 13,14,15,16,17,18,19.

(LIQUID)

MOLYBDENUM (Mo)

$$\Delta H_{298.15}^{\circ} = [7.076] \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = [6652 \pm 600] \text{ kcal/mol}$$

$$\Delta H_v^{\circ} = [140.812] \text{ kcal/mol}$$

$S_{298.15}^{\circ} = [9.261] \text{ gibbs/mol}$
 $T_m = 2892 \pm 10^{\circ}\text{K}$
 $T_b = [491.9^{\circ}\text{K}]$

Heat of Formation.

The ΔH_{298}° was obtained from that of the crystal plus ΔH_m° and the difference between $H_{2892}^{\circ} - H_{298}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity was estimated as 10 gibbs/mol in the real range in order to be comparable with the value in the crystal below the melting point. Below the melting point the heat capacity was assumed constant to a glass transition, assumed to be 2000°K, below which the heat capacity was that of the crystal. The entropy was obtained in a manner analogous to the heat of formation.

Melting Data.

The heat of melting was obtained from an entropy of melting of 2.3 eu assumed by comparison with Fe, Cu, Mg and Al. The melting point was reported by E. Rudy and S. Windisch, Aerojet-General Corporation, Report No. AFML-TR-65-2, Part 1, Vol. III, July 1965. A. G. Worthing, Phys. Rev. 25, 846 (1925), reports a melting point of 2895°K which, corrected to the 1948 International Temperature Scale, is 2882°K.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Heat of Formation

The heat of formation is simply the heat of sublimation at 298°K; this is obtained by second and third law analysis of several vapor pressure sets. A comparison of the results is tabulated below.

Reference	Method	Points	Range °K	2nd law $\Delta H^\circ_{298} \text{ kcal/mol}$	3rd law $\Delta H^\circ_{298} \text{ kcal/mol}$	Drift in 3rd law
1. Vozella	Langmuir	12	2140-2535	156.4 ± 2.9	157.6 ± 0.9	0.2 ± 1.3 eu
2. Edwards	Langmuir	9	2150-2460	146.7 ± 1.5	158.2 ± 1.2	5.0 ± 0.6 eu
3. Fries	Langmuir	12	2086-2489	156.5 ± 1.6	156.7 ± 0.7	0.1 ± 0.7 eu
4. Jones	Langmuir	9*	2113-2496	161.6 ± 3.8	156.0 ± 1.4	-2.6 ± 1.6 eu
5. Norris	Langmuir	Equn.	2000-2600*	131.1	148.6 ± 4.3	8.8 eu
6. Zwikker	Langmuir	Equn.	1200-2500*	159.1	156.2 ± 0.8	-0.8 eu
7. Babeliewsky	Mass Spec.		2220-2603*	149.6 ± 2.2		

* One point rejected due to failure of statistical test

The data of references 1 and 3 show no drift and thus indicate that the accommodation coefficient is essentially unity. A median value of the 3rd law heat is adopted as $157.3 \pm 0.5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The electronic energy levels are those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467, Washington D. C. (1959). Several individual lines missing from given terms were estimated by analogy with the observed lines in the term. In addition, an estimate of the values of completely missing terms, arising out of low lying multiplets, was made as follows: The 1D and 3P and 3D terms of the $[\text{Kr}] 4d^5s^2$ multiplet were estimated at 25000, 30000, 34000 and 36000 cm^{-1} . The triplet $^3P, ^3D$ and G levels and the singlet $^1D, ^1F$ and G levels of the $[\text{Kr}] 4d^6$ configuration were estimated at 30000 cm^{-1} and 40000 cm^{-1} respectively.

Higher configurations such as $[\text{Kr}] 4d^4s^2(6p) 5d$ which have many septuplet and quintuplet terms were thought to lie close to the ionization limit. However, upon calculating a table which contains an extra 100 levels at 35000 cm^{-1} and 200 levels each at 40000 and 45000 cm^{-1} , the difference in free energy function at 6000°K is a negligible 0.008 gibbs/mol.

MOLYBDENUM UNIPOSITIVE ION (Mo⁺) (IDEAL GAS) GFW = 95.9395

Ground State Configuration $s_{2,1/2}$ $\Delta H_f^\circ = 320.957 \text{ kcal/mol}$
 $S_{298.15}^\circ = 43.154 \text{ gibbs/mol}$ $\Delta H_f^\circ = 322.823 \text{ kcal/mol}$

Heat of Formation

The heat of formation is obtained by adding the heat of ionization to the heat of formation of the gas at 0°K. The heat of ionization, 163.742 kcal/mol (7.10 eV), is obtained from G. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington, D. C. (1958).

Heat Capacity and Entropy

The electronic energy levels are taken from C. E. Moore, loc. cit. The configuration [Kr] 4d⁵s² is completely missing in Mo⁺, while in the isoelectronic Nb(g) this is a very low lying configuration. However, a comparison of Cr⁺ with Mo⁺ and V(g) with Nb(g) indicates that the similarities are much closer down a given group than across a row to an isoelectronic neighbor. Thus, by analogy with Cr⁺, the missing configuration is expected to lie >50,000 cm⁻¹ and thus be negligible.

The enthalpy at 0°K is calculated to be -1.481 kcal/mol.

 $\sigma = 1$

Heat of Formation

The heat of formation, ΔH_f⁰298 (MoO, g) = 92.5 ± 15 kcal/mol, is derived from the heat of reaction, ΔH_r⁰298 = 32.9 kcal/mol for Mo(c) + O(g) + MoO(g) with all JANAF auxiliary data. The value of ΔH_f⁰298 is calculated by the third law method from the partial pressure data determined mass-spectrometrically in the temperature range from 2262 to 2466°K by G. DeMaria, et al. (1). The drift in the third law analysis is -14 ± 11 eu.

Heat Capacity and Entropy

The ground state configuration and the probable electronic levels are assumed to be similar to those for WO(g) (see JANAF WO(g) table of Sept. 30, 1966). T. M. Swaminathan and S. G. Krishnamurthy (2) observed ten band systems attributed to molybdenum oxide with lower state values of $\omega_e = 950 \pm 10 \text{ cm}^{-1}$. T. V. Iorns and F. E. Stafford (3) also observed a band with a peak at 969 cm⁻¹ in the vapor above MoO₃(c). It is surprising that the observed vibrational frequency of MoO(g) is lower than 1055 cm⁻¹ observed for WO(g). The latter comes not only from electronic spectra of the gas but also from infrared observation in matrix isolation; the former comes only from tentative assignments of electronic spectra presumably arising from MoO(g). It is possible that the observed states could be low lying excited states. We tentatively assume the fundamental vibrational frequency to be 955 cm⁻¹. The bond distance is then calculated by Guggenheimer's relation (4) for multiple bond molecules from the estimated vibrational frequency. The anharmonicity correction x_e is estimated from the relation $x_e^{1/2} = 0.014$ given by R. F. Barrow and A. D. Caunt (5). The constant (0.014) is assumed to be the same as that for WO(g). The value of α_e is calculated from the Morse potential function. The rotational constant B_e is calculated from the estimated bond distance.

MOLYBDENUM DIOXIDE (MoO₂)

(CRYSTAL)

GFW = 127.9388

S[°]_{298.15} = 11.96 ± 2 gibbs/mol
Td = Unknown
ΔH[°]_F = -139.3 ± 0.5 kcal/mol
ΔH[°]_{298.15} = -140.5 ± 0.5 kcal/mol

Heat of Formation

The adopted heat of formation, -140.5 kcal/mol, is a weighted average of values derived from calorimetric determinations, emf measurements and equilibrium studies. The results are given below.

Ignition of the bomb products from the calorimetric studies of Staskiewicz et al. indicated that oxidation was only about 70 per cent complete. The authors also digested the products with NH₄OH to remove the trioxide. The residue was the dioxide, as indicated by both oxidation and reduction. This evidence does not necessarily eliminate the possibility of known intermediate oxides in the combustion products. Mah found 72 - 75 per cent conversion to trioxide by weighing the total combustion products; he performed no additional analysis.

Heat Capacity and Entropy

E. G. King, J. Am. Chem. Soc. **80**, 1799 (1958), measured the low temperature heat capacities from 53.3° to 296°K. E. G. King, W. M. Waller and A. U. Christensen, U. S. Bur. Mines RI 5684, 1960, measured the high temperature enthalpy changes from 399° to 1801°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -1.3 to +0.7 percent, excluding the point at 1801°K. This point at the highest temperature deviates by +2.3 percent, which suggests that the apparent heat capacity is rising very rapidly. No explanation for this rapid rise is available.

The entropy S[°]₂₉₈ = 11.054 eu is obtained from the low temperature heat capacity data, based on S[°]₂₉₈ = 0.31 eu.

B. N. Figgis and J. Lewis, "Progress in Inorg. Chem.", Vol. **5**, page 123, Interscience Publishers, New York, 1964, indicated that MoO₂ is probably antiferromagnetic. Its small susceptibility is presumably due to Mo-Mo interactions. It is possible that at temperatures below 50°K entropy due to spin interactions of the d² electrons will appear, contributing up to 2.2 eu. The drifts in the equilibrium data do suggest that additional entropy may be appropriate; however, only the EMF data of Rapp appear to be sufficiently precise to influence the decision. These data suggest addition of 0.8 ± 0.1 eu and 0.9 ± 0.1 eu based on auxiliary data for Wüstite and NiO(c), respectively. We select the entropy of 11.954 eu from equilibrium data for NiO.

Heat of Formation

Burns et al. (1) have investigated mass-spectrometrically the vapor in equilibrium with powdered MoO₂(c) and also reported the partial pressures of MoO₂(g), MoO₃(g), (MoO₃)₂(g), and (MoO₃)₃(g). Second and third analyses of their partial pressure data are given in the table below. The adopted value, $\Delta H_f^\circ(\text{MoO}_2, g) = -3.1 \text{ kcal/mol}$, is calculated from their 3rd law value of $\Delta H_f^\circ = 137.4 \text{ kcal/mol}$ for MoO₂(c) + MoO₃(g), using all JANAF functions.

DeMaría et al. (2) have measured the partial pressures of gaseous oxides MoO, MoO₂, MoO₃ and O(g) in the Mo-Al₂O₃ system by mass spectrometry. Blackburn et al. (3) and Plante (4) have studied the vapor pressures above molybdenum dioxide(c) by the Knudsen effusion method. Second and third law analyses of these three sets of partial pressure data are reported in the following table.

Investigator	Reaction	Temp. °K	No. of Points	2nd law	3rd law	Drift	$\Delta H_f^\circ(\text{MoO}_2, g)$
1. Burns et al.	MoO ₂ (c) + MoO ₃ (g)	1598-1777	11*	137.9±3.1	137.38	-0.1±1.8	-3.1
2. DeMaría et al.	Mo(c) + 2O(g) + MoO ₂ (g)	2262-2466	11*	-61.8±32.1	-108.37	-19.9±13.6	10.7
3. Blackburn et al.	MoO ₂ (c) + MoO ₃ (g)	1818-2028	7	107.4±6.6	124.92	9.0±3.5	-15.6
4. Plante	MoO ₂ (c) + MoO ₃ (g)	1811-1802	6	149.5±13.0	140.92	-5.9±7.7	-0.4

Heat Capacity and Entropy

The MoO₂(g) is assumed to have a C_{2v} symmetry similar to that of TaO₂ reported by Weltner and McLeod (5). The bond angle O-Mo-O is estimated to be 110°. The bond distance Mo-O is estimated to be 1.80 Å, the same as that in MoO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectra of gaseous MoO₂Cl₂ and MoO₂Br₂, reported by Iorns and Stafford (6). The bending vibrational frequency (300 cm⁻¹) is estimated by comparison with other transition metal dioxides. The three principal moments of inertia are: I_A = 4.2470 × 10⁻³⁸, I_B = 11.5512 × 10⁻³⁸, and I_C = 15.7982 × 10⁻³⁸ g cm².

The electronic levels and quantum weights are estimated from the data reported by Weltner and McLeod (7) on W₂. The ground state is assumed to be ³A₁ and the first excited level is assumed to lie close to the observed transitions at 7800 Å and 7806 Å in W₂. Since both these states are presumed to be triplet, we have assigned a total degeneracy of 6. In addition, we expect from the electronic levels of Mo⁴⁺(g) (8) that other electronic states will also be found and these are arbitrarily estimated in the level at 25000 cm⁻¹.

S_{298.15} = 18.585 ± 0.15 gibbs/mol
 ΔH_f⁰ = -176.9 ± 0.1 kcal/mol
 ΔH_{298.15} = -178.1 ± 0.1 kcal/mol
 ΔH_m⁰ = 11.60 kcal/mol
 T_m = 1074°K

Heat of Formation

The adopted heat of formation, -178.1 kcal/mol, is the weighted average of two recent calorimetric determinations. The results are given below.

Staskiewicz et al. (2) found that oxidation was only about 80 per cent complete and tentatively attributed this to formation of MoO₃(c). The table for MoO₃(c) details the analytical methods applied to the combustion products and the heat of combustion of the dioxide which is necessary for reduction of the data of the trioxide. Combination of these investigations gives ΔH_f⁰ = -177.98 kcal/mol. Subsequent discovery of oxides intermediate between MoO₂ and MoO₃ raises a possible uncertainty concerning the incomplete oxidation. Mah (1) also reported that completion of the combustion of Mo(c) sample ranged from 84 to 93 per cent, as determined only by weight gain of the total combustion products upon prolonged low temperature ignition. In contrast, the earlier workers reported almost complete combustion. Neumann et al. (3) found about 97 per cent completion using a wet analysis involving aqua regia. Moose and Parr (4) found that in several combustions, they obtained over 99 per cent completion, based on the weight of the oxide formed.

Investigator	Year	Method	Reaction	ΔH _f ⁰ (kcal/mol)
1. Mah	1957	Calorimetric	Mo(c) + 3/2O ₂ (g) + MoO ₃ (c)	-178.16
2. Staskiewicz et al.	1955	Calorimetric	Mo(c) + 3/2O ₂ (g) + MoO ₃ (c)	-177.98
3. Neumann et al.	1934	Calorimetric	Mo(c) + 3/2O ₂ (g) + MoO ₃ (c)	-180.4
4. Moose and Parr	1924	Calorimetric	Mo(c) + 3/2O ₂ (g) + MoO ₃ (c)	-175.6

Heat Capacity and Entropy

Smith et al. (5) measured low temperature heat capacities from 18.3 to 299.8°K. King et al. (6) measured high temperature enthalpy data from 399.3° to 1063.9°K by drop calorimetry. The adopted heat capacities are derived from these two sets of data, subject to the constraint that there be a smooth joint at 298°K. Deviations of the enthalpy data from the adopted values are -0.65 percent to +0.17 percent. Seitz et al. (7) have also measured low temperature heat capacities from 70° to 298.7°K which are not in agreement with the values adopted. (The discrepancy has been discussed by Smith.) Cosgrove and Snyder (8) have also measured high temperature enthalpy data from 273° to 1068°K by drop calorimetry. Their smooth values are about 2 percent higher than the values adopted in the tabulation.

The entropy, S₂₉₈ = 18.585 eu, is obtained from the low temperature heat capacity data of Smith (5), based on S₀ = 0.197 eu. This starting entropy was obtained by the authors from a τ^2 extrapolation of the data. It is surprising that the entropy of MoO₃(c) is larger than that of WO₃(c) by about 0.4 eu. This may be due to the difference in the crystal structures, MoO₃ being orthorhombic and WO₃ monoclinic, and also to uncertainty in the entropy extrapolation below 50°K for WO₃(c).

Melting Data

The adopted melting point is obtained from King (6), and the heat of melting is calculated from the adopted enthalpies of the crystal and liquid based on the enthalpy data of King. Cosgrove and Snyder (8) found the melting point 1068°K by the cooling curve method, and derived ΔH_m⁰ = 12.54 kcal/mol from their smooth enthalpy values at the melting point.

MOLYBDENUM TRIOXIDE (MoO₃) (LIQUID)

S°_{298.15} = 26.971 gibbs/mol
Tm = 1074°
ΔH°_{298.15} = -168.555 ± 0.1 kcal/mol
ΔHm° = 11.80 kcal/mol

Heat of Formation
The heat of formation is calculated from that of the crystal by adding the heat of melting and the difference between H°₁₀₇₄ - H°₂₉₈ for the crystal and liquid.

Heat Capacity and Entropy
The heat capacity between the melting point and 1392.4°K is derived from the enthalpy data measured by E. G. King, W. W. Weiler and A. U. Christensen, U. S. Bur. Mines RI 5684 (1960). The heat capacity is assumed constant above and below the measured range. At 700°K, a glass transition is assumed, below which the heat capacity is taken to be the same as that of the crystal. The entropy at 298°K is obtained in a manner analogous to that of the heat of formation. L. A. Cosgrove and P. E. Snyder, J. Am. Chem. Soc. 75, 1227 (1953), also measured the enthalpy changes for MoO₃ (l) in the temperature range from 1068° to 1300°K. Their smooth values are ±2.5 percent to ±4.0 percent higher than our tabulated values. They have also found the melting point at 1068°K by the cooling curve method.

Melting Data
See JANAF MoO₃(c) table dated June 30, 1967.

Molybdenum Trioxide (MoO₃)

Heat of Formation

The dissociation energy of N₂ has been the subject of considerable controversy and is presented by A. G. Gaydon, "Dissociation Energies", Chapman and Hall, London, 1953. L. Brewer and A. W. Searcy, Ann. Rev. Phys. Chem., 7, 259 (1956), discuss extensive and varied experiments which have now fixed the value of 9.76 e.v. as being highly probable. Additional support for this value is afforded by the recently observed predissociation in the x \sum_g^+ state by A. Jortus, Nature 186, 302 (1960).

Heat Capacities and Entropies

The electronic levels noted above are listed by C. E. Moore, Nat. Bur. Standards (U.S.) Circ. 467, Vol. I (1949), Vol. III (1958).

Heat of Formation.

G. Herzberg, Molecular Spectra and Molecular Structure, I. Spectra of Diatomic Molecules, D. van Nostrand Co., Inc., New York, 1950, lists two $D_0(\text{NO})$ values, 5.296 and 6.487 e.v. A. G. Gaydon, Dissociation Energies and Spectra of Diatomic Molecules, Chapman and Hall, Ltd., London, 1953, lists $D_0(\text{NO}) = 6.49 \pm 0.05$ e.v. A Birge-Sponer extrapolation of the vibrational levels, up to $v = 19$, of the ground state leads to a D_0 of about 6.5 e.v. Gaydon's, loc. cit., analysis on the predissociation of NO also leads to the higher value for $D_0(\text{NO})$.

Y. Tanaka, J. Chem. Phys. 22, 2045 (1954), has observed and analyzed the emission bands of NO in the vacuum ultraviolet region. Tanaka's, loc. cit., observation and interpretation of the abrupt cutoff (predissociation) of certain v' values in the β , δ , and ϵ bands and of the complete non appearance of ϵ and β bands strongly favors a $D_0(\text{NO}) = 6.48$ e.v. ΔH_f^0 298.15 (NO)G was calculated on this basis to be 22.033 ± 1 kcal. mole⁻¹.

More recently M. A. Frisch, Diss. Abstr. 23, 1940 (1961), Thesis, University of Wisconsin, Madison, Wisconsin, 1962, has calorimetrically determined the heat of reaction for

at 298.15°K , from which the author derives a ΔH_f^0 298.15 NO(g) = 21.58 ± 0.04 kcal. mole⁻¹. The auxiliary values used by Frisch to calculate the heat of formation of nitric oxide were based upon the 1961 atomic weight scale. Recalculating ΔH_f^0 298.15 NO(g) using auxiliary functions based on the 1956 atomic weight scale had a negligible effect on the final result.

The calorimetrically determined heat of formation for nitric oxide, 21.58 ± 0.04 kcal. mole⁻¹, was selected as the best value.

Heat Capacity and Entropy.

The spectroscopic constants were taken from R. H. Gillette and E. H. Eyster, Phys. Revs. 59, 1113 (1959), who measured and analyzed the fundamental rotation-vibration band of nitric oxide using a grating spectrometer. The constants used in this calculation were adjusted to correspond to the naturally occurring isotopic mixture.

Heat of Formation.

K. Mettenberg, *J. Chem. Phys.* **22**, 1564 (1954), and W. C. Walker and O. L. Weisauer, *J. Chem. Phys.* **23**, 1982 (1955), have measured the ionization potential of NO(g) by photoelectron spectroscopy, yielding $I.P. = 9.25 \pm 0.02$ and 9.20 ± 0.03 eV, respectively. H. D. Hagstrum, *J. Chem. Phys.* **23**, 1178 (1955), reported $I.P. = 9.4 \pm 0.2$ eV by electron impact. K. F. Huber, *Helv. Phys. Acta* **34**, 929 (1961), determined spectroscopically the ionization potential for NO(g). $I.P. = 9.267 \pm 0.005$ eV (213.72 \pm 0.1 kcal/mol). The last value has been selected, and yields the heat of formation of $\text{NO}^+(\text{g})$, $\Delta H_f^\circ = 235.18$ kcal/mol, using $\Delta H_f^\circ(\text{NO}, \text{g}) = 21.46 \pm 0.04$ kcal/mol.

Heat Capacity and Entropy.

The selected molecular constants were obtained from the ultraviolet spectra by E. Miescher, Can. J. Phys. 33, 355 (1955). *Helv. Phys. Acta* 29, 135 (1956).

The tabulated thermodynamic functions are in reasonable agreement with those calculated by J. Hilsenrath and Carla G. Messina, NBS Report 8504, July 1, 1964, who have used slightly different molecular constants.

Heat of Formation.

The equilibrium constants for $\text{NO(g)} + 1/2 \text{O}_2 \rightarrow \text{NO}_2\text{(g)}$ of Bodenstein and Lindner, Zeits. fur physik. Chem. 100, 82 (1922) as given by W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) were subjected to 2nd and 3rd law analysis. Third law analysis gave $\Delta H_{298} = -13.67 \text{ kcal.}$ and 2nd law $\Delta H_{298} = -13.52 \pm 0.01 \text{ kcal.}$ The third law value had a very slight trend with temperature which was consistent with an entropy error of 0.25 cal. deg.⁻¹ mole⁻¹, the second law

entropy was also consistent with an entropy error of 0.25 cal. deg.⁻¹ mole⁻¹. However the functions for all three gases are well established to about 0.03 cal. deg.⁻¹ mole⁻¹ or better and so this must be interpreted as due to errors in the data. On this basis the 3rd law value of the heat was chosen and combined with JANAF auxiliary data to give $\Delta H_f^{298} = 7.91 \pm 0.2 \text{ kcal. mole}^{-1}$, where the uncertainty includes that due to the possible error in the equilibrium constants.

Heat Capacity and Entropy.

O. R. Bird, J. C. Baird, A. W. Jache, J. A. Hodgeson, R. F. Curl Jr., A. C. Kunkle, J. W. Evansford, J. Rastrop-Andersen and J. Rosenthal, J. Chem. Phys. 40, 3378 (1964) have given a complete review of the microwave spectrum of NO₂. They also give a corrected infrared vibrational assignment, adopted here, which is in excellent agreement with calculations from the microwave data. They report $I_A = 0.34981 \times 10^{-39} \text{ g. cm.}^2$ and $I_B = 6.45446 \times 10^{-39} \text{ g. cm.}^2$ and $I_C = 6.81994 \times 10^{-39} \text{ g. cm.}^2$. The bond length and angle were chosen to give the best fit of the moments of inertia.

NITROGEN DIOXIDE UNINEGATIVE ION (NO_2^-) (IDEAL GAS)

Point Group C_{2v}
 $S_{298.15}^0 = [56.5] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $S_{298.15}^0 = -85.9 \pm 12 \text{ kcal. mole}^{-1}$
 Ground State Quantum Weight = 1

$\Delta H_f^0 = -85.7 \pm 12 \text{ kcal. mole}^{-1}$
 $\Delta F_f^0 = -85.9 \pm 12 \text{ kcal. mole}^{-1}$

Vibrational Frequencies and Degeneracies

ω , cm. ⁻¹
[1320] (1)
[750] (1)
[1220] (1)

$\sigma = 2$

Bond Distances: N-O = $[1.23] \text{ \AA}$
 Bond Angle: O-N-O = $[116]^\circ$
 Product of the Moments of Inertia: $I_A I_B I_C = [25.6905] \times 10^{-117} \text{ g.}^3 \text{ cm.}^6$

Heat of Formation.

The heat of formation of $\text{NO}_2^-(g)$ was calculated from the electron affinity of $\text{NO}_2(g)$ and the JANAF value of ΔH_f^0 for $\text{NO}_2(g)$, $4.0 \pm 0.5 \text{ ev}$ and $8.6 \pm 0.2 \text{ kcal. mole}^{-1}$, respectively. The former was obtained from the National Bureau of Standards Report 6820, "Preliminary Report on the Thermodynamic Properties of Selected Light Element and Some Related Compounds", January 1965.

Heat Capacity and Entropy.

The bond distance N-O and the angle O-N-O of $\text{NO}_2^-(g)$ were estimated to be the same as those in $\text{NaNO}_2(c)$ which have been determined by G. B. Carpenter, Acta Cryst. 5, 132(1952). The three individual moments of inertia are $I_A = [0.6872] \times 10^{-39} \text{ g. cm.}^2$, $I_B = [5.7804] \times 10^{-39} \text{ g. cm.}^2$ and $I_C = [6.4676] \times 10^{-39} \text{ g. cm.}^2$

The vibrational frequencies of $\text{NO}_2^-(g)$ were assumed to be the same as those for nitrite ion in solution which have been measured by D. Williams, J. Am. Chem. Soc. 61, 2987(1939). These measured frequencies in nitrite solution are comparable to those in $\text{NO}_2(g)$ (1357.8, 756.8 and 1665.5 cm.⁻¹), reported by G. R. Bird et al., J. Chem. Phys. 40, 3378 (1964).

 Product of the Moments of Inertia: $I_A I_B I_C = [5.309 \times 10^{-115}] \text{ g. cm.}^6$
 $\sigma = [6]$

Heat of Formation.

The heat of formation is based on equilibrium constants for the reaction $\text{N}_2\text{O}_5(\text{g}) \rightarrow \text{NO}_2(\text{g}) + \text{NO}_3(\text{g})$ obtained from shock wave studies by Schott and Davidson, J. Am. Chem. Soc. 80, 1941 (1958). These equilibria give a second law value of $\Delta H_f^o 495 = 21.5 \pm 1.4 \text{ kcal.}$, corresponding to $\Delta H_f^o 298.15 = 22.2 \text{ kcal.}$, and a third law value of $\Delta H_f^o 298.15 = 22.2 \text{ kcal.}$. The resulting heat of formation is $17.0 \text{ kcal. mole}^{-1}$.

Quillory and Johnston, J. Am. Chem. Soc. 85, 1695 (1963) report an equilibrium constant based on estimated Beer's law constants for NO₃ and attributed to the reaction $\text{O}_2 + \text{NO} \rightarrow \text{NO}_3$. This gives a third law heat of formation of $12 \pm 2 \text{ kcal. mole}^{-1}$, which was not considered. A tentative value of $23 \text{ kcal. mole}^{-1}$ (or greater) may be derived from the D₀ given by D. A. Ramsay, Proc. 10th Colloq. Spect. Internl. (1962), Univ. Maryland, pp. 583-596, 1963.

Heat Capacity and Entropy.

The structure and frequencies are those estimated by I. C. Haataune, J. Phys. Chem. 65, 2249 (1961). A symmetry of D_{3h} was chosen on the basis of Valan's correlation, J. Chem. Soc. 1953, 2301 (1953) and the bond distance was taken as 2% longer than in the nitrate ion. The planar mode frequencies were calculated from estimated Urey-Bradley force constants, while the out-of-plane wagging frequency (765 cm.⁻¹) was assumed the same as in HNO₃(g).

There are several conflicting bits of information concerning NO₃ radicals. Chantry, Horsfield, Morton and Whiffen, Mol. Phys. 5, 589 (1962) studied the electron resonance and optical absorption spectra of what appear to be NO₃ radicals trapped in crystals of urea nitrate. The authors suggest a planar structure without a threefold axis (thus C_{2v} symmetry), at least for the trapped radicals. Quillory and Johnston, loc. cit., report for gaseous NO₃ radicals an infrared frequency at 1840 cm.⁻¹ which they assign as the N-O stretch. The similarity of this frequency to those in N-O and X-N-O molecules led the authors to suggest an OONO structure (thus C_{2v} symmetry) rather than the nitrate structure. The remaining frequencies for such a structure may be crudely estimated by analogy with those measured for (NO₂)₂ by Smith, Keller and Johnston, J. Chem. Phys. 19, 189 (1951). Based on such frequencies and reasonable bond distances, the room temperature entropy for the OONO structure would be 68-72 cal. deg.⁻¹ mole⁻¹. Such an entropy is quite inconsistent with the second law $\Delta S_f^o 495 = 33.2 \pm 3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ for $\text{H}_2\text{O}_2(\text{g}) \rightarrow \text{NO}_2(\text{g}) + \text{NO}_3(\text{g})$ obtained from the shock wave studies of Schott and Davidson. The Haataune functions based on the nitrate structure were selected because they are consistent with the experimental entropy. The principal moments of inertia for this structure are $I_A = 6.427 \times 10^{-39}$, $I_B = 6.427 \times 10^{-39}$ and $I_C = 12.853 \times 10^{-39} \text{ g. cm.}^2$. A structure of C_{2v} symmetry would result if the nitrate structure were distorted to give one non-equivalent oxygen. Ramsay, loc. cit., suggests that such distortion can only be small, based on the high dispersion optical spectra of the gas phase.

$\omega_e = 1337.24 \text{ cm.}^{-1}$
 $\omega_e x_e = 6.993 \text{ cm.}^{-1}$
 $B_e = 0.7862 \text{ cm.}^{-1}$
 $\alpha_e = 0.00557 \text{ cm.}^{-1}$
 $D_e = 1.09 \times 10^{-6} \text{ cm.}^{-1}$
 $r_e = 1.4910 \text{ \AA}$
 $\sigma = 1$

Heat of Formation.

The selected ΔH_f^o 298.15 was calculated from the $D_0^o = 165.8 \pm 1.2 \text{ kcal. mole}^{-1}$ reported by R. L. Potter and V. N. Distefano, J. Phys. Chem., **65**, 849 (1961). $A D_0^o = 163.7 \pm 1.2 \text{ kcal. mole}^{-1}$ was experimentally determined by E. O. Huffman, G. Tarbuton, K. L. Elmore, W. E. Cate, H. K. Walters, Jr., and G. V. Elmore, J. Am. Chem. Soc., **76**, 6239 (1954). The D_0^o reported by Huffman et al. was derived using a pressure-composition method i.e. measurement of equilibrium vapor pressure at 1173°K for the reaction $[\text{PN}(g) \rightarrow \text{P}_2(g) + \text{N}_2(g)]$. Potter and Distefano (loc. cit.) recalculated Huffman's results to obtain their D_0^o value. A. G. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", Chapman and Hall (1953), lists a $D_0^o = 138.4 \pm 19 \text{ kcal. mole}^{-1}$. The corresponding heats of formation are:

ΔH_f^o 298.15	Source
$25.0 \pm 1.2 \text{ kcal. mole}^{-1}$	Potter and Distefano (loc. cit.)
$27.1 \pm 1.2 \text{ kcal. mole}^{-1}$	Huffman et al. (loc. cit.)
$53 \pm 19 \text{ kcal. mole}^{-1}$	Gaydon (loc. cit.)

Heat Capacity and Entropy.

The molecular constants are taken from G. Herzburg, "Diatomic Molecules," D. Van Nostrand Co., New York, N. Y., (1960) 2nd Ed.

 $\omega_e = [0.7762] \text{ cm.}^{-1}$
 $\alpha_e = [0.0064]$
 $r_e = 1.495(\text{?}) \text{ \AA}$

Heat of Formation

The dissociation energy is listed by A. O. Gaydon, "Dissociation Energies and Spectra of Diatomic Molecules", 2nd Edn., Chapman and Hall, London (1955).

Heat Capacity and Entropy

The spectroscopic constants other than B_e and α_e are from O. Herzberg "Spectra of Diatomic Molecules", 2nd Edn., D. Van Nostrand Company, New York (1950). r_e is from "Tables of Interatomic Distances and Configuration in Molecules and Ions", The Chemical Society, London (1958), and has been used, together with the equation to calculate B_e and α_e .

$$\alpha_e = \frac{6}{\omega_e} \left(\frac{D_0 x_e B_e^3}{\omega_e} - 6B_e^2 / \omega_e \right) \quad (\text{Herzberg, op. cit., p. 108})$$

SILICON NITRIDE (SiN)

(IDEAL GAS)

OPW = 42.0927

Ground State Configuration 2 Σ⁺

ΔH_f^o = 89.7 ± 15 kcal/mol

ΔH_f^o = 89 ± 15 kcal/mol

S_{298.15} = 51.792 gibbs/mol

Electronic Levels and Quantum Weights

ci, cm ⁻¹	ΔE
0	2
[6000]	4
24299.4	2
[31000]	4

ω_e = 1150.8 cm⁻¹
 ω_ex_e = 6.55 cm⁻¹
 B_e = 0.7299 cm⁻¹
 α_e = 0.00567
 σ = 1
 r_e = 1.578 Å

Heat of Formation

A linear Birge-Sponer extrapolation of the ground state gives a dissociation energy of 142.9 kcal. The ground state can correlate with normal atoms Si(³P) + N(²D); in this latter case D₀ would be 68 kcal. The uncertainty in the extrapolation is quite large, ± 30 kcal, since only 6 levels, of the estimated total of 87 levels, are observed.

A dissociation energy can also be calculated from the B²Σ⁺ state by a much shorter extrapolation. This extrapolation is done graphically since some curvature is evident in the first six levels. A value of D₀(B²Σ) = 50.4 kcal is obtained. This corresponds to D₀(X²Σ) = 119.9 kcal for normal products or D₀(X²Σ) = 65 kcal for excited nitrogen as a product. The uncertainty in this extrapolation is less than the ground state and is probably ± 20 kcal.

An estimate of D₀(SiN) may be obtained by equating D₀(SiN)/D₀(SiO) = D₀(CN)/D₀(CO); this yields D₀(SiN) = 135 kcal. A comparison of the isoelectronic molecules CP, BS and BeCl and the related molecules CN, BO, BeF indicates D₀(SiN) > 115 kcal.

A value of D₀(SiN) = 130 ± 15 kcal/mol is in agreement within the uncertainties of both ground state and B state extrapolations assuming normal atoms as products, and is in agreement with the other estimates. This value is adopted and yields ΔH_f^o = 89 kcal/mol.

Heat Capacity and Entropy

The B-X transition has been reported by R. A. Jenkins and H. de Lae, Proc. Roy. Soc. (London) 122, 103 (1929). The rotational and vibrational constants are derived from their work and adjusted to normal isotopic abundance. The A²Π-²Σ⁺ transition has been observed by M. D. Shetler, Ph.D. Thesis, Univ. of California, Berkeley (1965). The height of the A state is estimated by correlation with CF(g). The level of the B state is taken from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., 2nd Edition, New York, 1950.

ΔH°₀ = -79.8 ± 1 kcal/mol
 ΔH°_{298.15} = -80.7 ± 1 kcal/mol
 ΔH°_m = [16] kcal/mol

S°_{298.15} = 7.23 ± 0.05 gibbs/mol
 T_m = 3220 ± 50°K

Heat of Formation

Humphrey (1) and Neumann et al. (2) determined the heat of combustion of titanium nitride by burning the material in an oxygen bomb calorimeter. For reaction (a) Humphrey obtained ΔH°₂₉₈ = -145.05 ± 0.14 kcal/mol and Neumann et al. ΔH°₂₉₈ = -145.0 kcal/mol. From an examination of the combustion products Humphrey reported that the TiO₂ was >95 per cent rutile and <5 per cent anatase, but made no correction for the anatase. The adopted ΔH°₂₉₈ = -80.7 kcal/mol is the average of three values, two from Humphrey (-80.75, -80.61), one as reported, and one corrected for anatase, and one from Neumann et al. (-80.8). The uncertainty in the adopted heat is due mainly to the uncertainty in the heat of formation of rutile. Hoch et al. (3) determined the vapor pressure of reaction (b), in the temperature range 1987-2241°K, using a Knudsen effusion method. Third law analysis of the data yields a ΔH°₂₉₈ = -79.5 ± 9 kcal/mol. Linevsky (4) obtained the titanium partial pressures of reaction (c) (2088-2141°K) at fixed nitrogen pressures using atomic absorption spectroscopy. Third law analysis of the data gives a ΔH°₂₉₈ = -81 ± 18 kcal/mol. These equilibrium measurements were not considered in deriving the heat of formation due to their large uncertainties in comparison to the calorimetric data.

Heat Capacity and Entropy

Low temperature heat capacities are from the data (52-296°K) of Shomate (5). Naylor (6) measured high temperature heat contents (388-1738°K). High temperature heat capacities are derived from the enthalpies by a fitting technique which constrains the curve to join smoothly with the low temperature values. Above 1738°K the heat capacity is graphically extrapolated. The entropy is based on S°₀ - S°₀ = 0.138 eu.

Melting Data

See liquid table.

Reference	Method	Reaction	T°K	ΔH° ₂₉₈ kcal/mol	ΔH° ₂₉₈ kcal/mol
1	Calorimeter	(a) TiN(c) + O ₂ (g) → TiO ₂ (rutile) + 1/2N ₂ (g)	298	-145.05±.14	-80.75
1	Calorimeter	(a) TiN(c) + O ₂ (g) → TiO ₂ (rutile) + 1/2N ₂ (g)	298	-145.05±.14	-80.61*
2	Calorimeter	(a) TiN(c) + O ₂ (g) → TiO ₂ (rutile) + 1/2N ₂ (g)	298	-145.0	-80.80
3	Equilibrium	(b) TiN(c) + Ti(g) → 1/2N ₂ (g)	1987-2241	212±9	-79.5
4	Equilibrium	(c) TiN(c) → Ti(g) + 1/2N ₂ (g)	2088-2141	230±17	-81.2

*Assumes that the product TiO₂ is 95 per cent rutile and 5 per cent anatase.

(Liquid) GFW = 61.9067

TITANIUM NITRIDE (TiN) (LIQUID) GFW = 61.9067

 $S^{\circ}_{298.15} = [12.603] \text{ gibbs/mol}$ $\Delta H^{\circ}_{298.15} = [-63.531 \pm 1.1] \text{ kcal/mol}$ $\Delta H_m^{\circ} = [16] \text{ kcal/mol}$ $T_m = 3220 \pm 50^{\circ}\text{K}$

Heat of Formation

The heat of formation is obtained from $\Delta H^{\circ}_{298}(c)$ by adding ΔH_m° and the difference between $H_m^{\circ} - H^{\circ}_{298}$ for crystal and liquid.

Heat Capacity and Entropy

A glass transition is assumed at 2200°K . Below 2200°K the heat capacity is obtained from the heat capacity of the crystal. Above 2200°K it is assumed constant and estimated as 15 gibbs/mol or 7.5 gibbs/g-atom. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

T_m is taken from C. Agte and K. Moers, Z. Anorg. Allgem. Chem. 198, 233-43 (1931). ΔH_m° is derived from an estimated $\Delta S_m = 2.5 \text{ gibbs/g-atom}$ as suggested by O. Kubaschewski, E. L. Evans and C. B. Alcock, "Metallurgical Thermochemistry," Pergamon Press, New York, 1967.

NZr

MONOZIRCONIUM MONONITRIDE (ZrN) (crystal)

Mol. Wt. = 105.228
 $\Delta H_f^0 = -86.5 \pm 2 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 \text{ 298.15} = -87.3 \pm 2 \text{ kcal. mole}^{-1}$
 $T_m = [3225^\circ\text{K}]$
 $S_{298.15}^0 = 9.29 \pm 0.05 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_m^0 = [16.1] \text{ kcal. mole}^{-1}$

Heat of Formation. The heat of reaction I, $-174.25 \pm 0.30 \text{ kcal. mole}^{-1}$, was measured by A. D. Meh and N. L. Gelbert. The $\Delta H_f^0 \text{ 298.15}$ of ZrN was obtained using $-261.5 \pm 0.2 \text{ kcal. mole}^{-1}$ for $\Delta H_f^0 \text{ 298.15}$ of ZrO_2 . For the same reaction B. Neumann, C. Kroger and H. Kunz, Z. anorg. Chem. 218, 379 (1934) obtain $-176.0 \text{ kcal. mole}^{-1}$ on a sample of unspecified purity. Vapor pressure measurements of M. Hoch, D. P. Dingley and H. L. Johnston, J. Am. Chem. Soc. 77, 304 (1955) lead to $-81 \text{ kcal. mole}^{-1}$ for the $\Delta H_f^0 \text{ 298.15}$ of ZrN. However, this value is uncertain by 10% as evidenced by the work on ZrO_2 by W. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 25, 1207 (1957).

(I) $\text{ZrN(c)} + \text{O}_2(\text{g}) = \text{ZrO}_2(\text{c}) + 1/2 \text{ N}_2(\text{g})$

Heat Capacity and Entropy. Low temperature measurements, 53-297°K, of S. S. Todd, J. Am. Chem. Soc. 72, 2914 (1950), were smoothly joined to those of J. P. Coughlin and E. G. Kings, J. Am. Chem. Soc. 72, 2282 (1950), 298-1075°K.

Melting. Estimated by C. B. Henderson and R. S. Scheffer, Atlantic Research Corp., Alexandria, Va., "Survey of Thermochemical Data", January, 1960.

MONOZIRCONIUM MONONITRIDE (ZrN) (Liquid)

Mol. Wt. = 105.228
ΔH_f^o 298.15 = [-59.5] cal. deg.⁻¹ mole⁻¹
T_m = [3225]°K
ΔH_m^o = [16.1] kcal. mole⁻¹

Heat of Formation. Calculated from the solid.

Entropy. Calculated from the solid.

Heat Capacity. The heat capacity function of the solid was assumed to approximate those of the liquid up to the estimated glass point of 2150°K. Above the glass point the heat capacity was estimated.

Monozirconium Mononitride (ZrN)

June 30, 1963

MONOZIRCONIUM MONONITRIDE (ZrN)

(IDEAL GAS)

MOL. WT. = 105.228

Ground State Configuration [2 Σ] $\Delta H_f^o = [169.4] \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = [55.78] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^o = [170.5] \text{ kcal. mole}^{-1}$
 $S_{298.15}^o = [55.78] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

Electronic Levels and Multiplicities

$$\frac{G_u}{G_l} \text{ cm.}^{-1} \quad \frac{G_u}{G_l} \quad \frac{G_u}{G_l}$$

$$\omega_e = [840] \text{ cm.}^{-1} \quad \omega_e^x = [5] \text{ cm.}^{-1} \quad \epsilon = 1$$

$$r_e = [1.83] \text{ \AA}$$

Heat of Formation.

ΔH_f^o was estimated as 170.7 kcal. mole⁻¹ by J. S. Gordon, AstroSystems International, Livingston, New Jersey, private communication, January 10, 1963. ΔH_f^o 298.15 was then calculated.

Heat Capacity and Entropy.

Molecular constants were estimated by J. S. Gordon, loc. cit. r_e was calculated from the relationship $r_e = (16.858778 / \mu^{1/2} B_e)^{1/2} \text{ \AA}$.

Dec. 31, 1960; Mar. 31, 1961; Sept. 30, 1965

NITROGEN, DIATOMIC (N₂) (IDEAL GAS - REFERENCE STATE) MOL. WT. = 28.0134

Ground State Configuration $1 \sum^+ g$
 $\Delta H_f^o = 0$
 $S_{298.15}^o = 45.77 \pm 0.01$ cal. deg.⁻¹ mole⁻¹
 $\Delta H_f^o 298.15 = 0$
 $\omega_e x_e = 14.059$ cm.⁻¹
 $\omega_e = 0.01791 \pm 0.0001$ cm.⁻¹
 $B_e = 1.9825$ cm.⁻¹
 $r_e = 1.08758 \pm 0.0001$ Å
 $\sigma^- = 2$

Heat of Formation.

The heat of formation (ΔH_f^o) for N₂(g) is zero at all temperatures by definition.

Heat Capacity and Entropy.

The functions adopted here are based on the direct summation calculations of L. Glatf, J. Beizer and H. L. Johnston, Ohio State Univ. Res. Found. Proj. 316, Report No. 9, 1953. They calculated the functions for N₂ by a direct summation using spectroscopic data given by G. Herzberg, "Diatomic Molecules", D. Van Nostrand Co., New York, 1950. The entropies were changed by -Ring to remove the effects of nuclear spin included by Glatf, Beizer, and Johnston, and by 0.012 for the difference in spectroscopic constants. J. A. Goff and S. Grotch, Trans. Am. Soc. Mech. Engrs., 72, 741 (1950), calculated a set of functions by a direct summation over the ground state levels only. Agreement with the functions of Glatf, Beizer, and Johnston is within 0.1%.

B. P. Stoicheff, Can. J. Phys. 32, 630 (1954), determined the spectroscopic constants of N₂ by combining his measured rotational spectra with the results of band spectra given in the literature. The constants listed above have been corrected to apply to the naturally occurring isotopic composition listed by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys., 30, 585 (1958).

Bond Angles O-N-N (nitroso) = 110° O-N-O = 134°

Product of Moments of Inertia I_AI_BI_C = 4.6201 X 10⁻¹¹⁴ g.³ cm.⁶

Heat of Formation.

Equilibria for the reaction N₂O₃(g) → NO(g) + NO₂(g) have been studied by Beattie and Bell, J. Chem. Soc. 1957, 1681 (1957), Verhoek and Daniels, J. Am. Chem. Soc. 53, 1250 (1931) and Abel and Proia, Z. Elektrochem. 35, 712 (1929).

The results of Beattie and Bell are the most extensive, but they depend on the early analysis of Glaue and Kemp, J. Chem. Phys. 2, 40 (1938), for the simultaneous equilibrium N₂O₄(g) → 2NO₂(g). The JANAF analysis of the tetroxide dissociation has been used to recalculate the data of Beattie and Bell. Non-ideality of N₂O₄ and NO₂ was allowed for by use of the equations of state of Glaue and Kemp, while non-ideality of NO and N₂O₃ was removed by extrapolation of the equilibrium constants to zero pressure in a manner similar to that of Beattie and Bell. The data of Verhoek and Daniels and of Abel and Proia have not been recalculated. Second and third law analyses of the results are summarized below. The heat of formation was obtained from ΔH_f⁰ 298 = 9.70 kcal. mole⁻¹.

Source	Temp. Range °K.	T °K.	Third Law ΔS _T (cal. deg. ⁻¹ mole ⁻¹)	Second Law ΔS ₂₉₈ (kcal. mole ⁻¹)	Third Law ΔH _f ⁰ 298 (kcal. mole ⁻¹)

a) Given by authors

b) From author's K_p values

c) From recalculated K_p values

Heat Capacity and Entropy.

The functions are similar to those calculated by I. C. Hirst, J. Phys. Chem. 65, 2249 (1961), based on the analysis of Devlin and Hirst, Spectrochim. Acta 17, 218 (1961), of the Raman and infrared spectra in terms of Urey - Bradley force constants. Devlin and Hirst used observed isotopic shifts in the spectra along with force constants transferred from nitrogen oxides and oxyhalides in order to select the N-N bond distance and the O-N-N bond angle.

The unobserved mode was assumed to be free internal rotation around the N-N bond, leading to S₂₉₈ = 73.91 cal. deg.⁻¹ mole⁻¹ which is in good agreement with 74.15 ± 0.52 cal. deg.⁻¹ mole⁻¹ obtained from the recalculated second law of Beattie and Bell. The principal moments of inertia are I_A = 22.694 X 10⁻³⁹, I_B = 29.577 X 10⁻³⁹, and I_C = 6.883 X 10⁻³⁹ g. cm.², while the reduced moment for internal rotation was calculated as I_r = 0.990 X 10⁻³⁹ g. cm.².

Heat of Formation.

The heat of formation was back calculated from that of the liquid using the measured heat of melting and the enthalpy of the crystal and liquid.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) measured the low temperature heat capacity from 15-295°K. The entropy was obtained by integration of this data using $S_{15} = 0.34 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

The temperature and heat of melting were also measured by Giauque and Kemp, loc. cit.

Heat of Formation.

The heat of formation was back calculated from that of the gas using the calorimetrically measured heat of vaporization to the equilibrium mixture, in conjunction with a dissociation constant $\alpha_c = 0.161$.

Heat Capacity and Entropy.

W. F. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) measured the low temperature heat capacity from 15° to $295^\circ K.$, above $295^\circ K.$ the heat capacity was smoothly extrapolated.

Melting and Vaporization Data.

Giauque and Kemp, loc. cit. measured the temperature and heat of melting and also the boiling point and the calorimetric value of the heat of vaporization to the equilibrium mixture. The heat of vaporization to a hypothetical pure N_2O_4 gas at $294.25^\circ K.$ was calculated to be $6.91 \text{ kcal. mole}^{-1}$.

σ = 4

Heat of Formation.

W. P. Giauque and J. D. Kemp, J. Chem. Phys. 6, 40 (1938) calculated idealized equilibrium constants for the reaction N₂O₄(g) = 2NO₂(g) from the work of Bodenstein and Bode (1), Zeits. fur physik. Chem. 100, 75 (1922), Verboek and Daniels (2), J. Am. Chem. Soc. 53, 1250 (1931) and Woutzel (3), Compt. Rend. 169, 1397 (1919). The second and third law analysis of these equilibrium constants has been reported using more recent functions. The results are shown below.

Ref.	Third Law ΔH ₂₉₈	Second Law ΔH ₂₉₈
1.	13.644	13.634 ± 0.015*
2.	13.672	14.429 ± 0.126
3.	13.657	13.599 ± 0.019**

* Ten points rejected because of statistically significant scatter.

** One point rejected.

The second law value of Verboek and Daniels was not considered significant due to the extremely small temperature range and the use of only three temperatures. The adopted value was 13.65 ± 0.03 kcal. which leads to 2.17 kcal. mole⁻¹ for the heat of formation of N₂O₄(g).

Heat Capacity and Entropy.

The structural parameters were taken from the electron diffraction measurements of D. W. Smith and K. Hedberg, J. Chem. Phys. 25, 1282 (1956). The vibrational frequencies are those chosen by I. C. Hataatune, J. P. Devlin and Y. Wada, J. Chem. Phys. 33, 714 (1960). The torsional frequency of 50 cm.⁻¹ was estimated in order to bring the entropy of the gas into agreement with that determined by Giauque and Kemp loc. cit. From low temperature heat capacities and heats of fusion and vaporization. The individual moments of inertia were I_A = 12.508 X 10⁻³⁹ g. cm.², I_B = 22.809 X 10⁻³⁹ g. cm.², and I_C = 35.117 X 10⁻³⁹ g. cm.²

Heat of Formation.

The heat of formation was obtained by recalculation of the calorimetric data of Ray and Ogg for the reaction of $\text{N}_2\text{O}_5(\text{g})$ with NO. The stoichiometry of the reaction products, originally based on the results for $\text{N}_2\text{O}_4 \rightarrow 2 \text{NO}_2$ from Diaque and Kemp, J. Chem. Phys. 5, 40 (1938), was based on the JANAF analysis of this simultaneous equilibrium. A correction of 0.29 kcal. was made in the heat of reaction because of the additional formation of N_2O_3 from NO and NO_2 .

Confirmation of the heat of formation was obtained by combination of the heats of hydrolysis and sublimation of $\text{N}_2\text{O}_5(\text{c})$. The results are summarized below. Second law values are given for the heats of sublimation, but third law analyses suggest that the value from Russ and Pokorny is more reliable. Most of the uncertainty in this path, however, arises from the heat of hydrolysis.

Source	Method	Reaction	ΔH_f° 298.15 (kcal. mole ⁻¹)	ΔH_f° 298.15 (kcal. mole ⁻¹)
1	Calorimetric	$\text{N}_2\text{O}_5(\text{g}) + \text{NO}(\text{g}) \rightarrow \text{N}_2\text{O}_4(\text{g}) + \text{NO}_2(\text{g}) + 1.138 \text{ N}_2\text{O}_4(\text{g})$	-16.05 ± 0.20	2.67
2	Calorimetric	$\text{N}_2\text{O}_5(\text{c}) + \text{H}_2\text{O}(\text{l}) \rightarrow 2 \text{HNO}_3(\text{aq})$	-20.2 ± 0.5	—
3	Vapor Pressure	$\text{N}_2\text{O}_5(\text{c}) \rightarrow \text{N}_2\text{O}_5(\text{g})$	13.37 ± 0.06	2.79*
4	Vapor Pressure	$\text{N}_2\text{O}_5(\text{c}) \rightarrow \text{N}_2\text{O}_5(\text{g})$	13.25 ± 0.12	2.67*

*Using reaction 2 and ΔH_f° 298.15 = -68.35 (H₂O, l), -49.55 (HNO₃, aq)

Heat Capacity and Entropy.

Ray and Ogg, J. Chem. Phys. 25, 384 (1957) reported $S_{298.15}^\circ = 85 \pm 0.5 \text{ cal. deg. mole}^{-1}$ from combination of kinetic and thermochemical values. This entropy was recalculated as follows. The rate data of Ray and Ogg, loc. cit., and of Daniels and Johnston, J. Am. Chem. Soc. 43, 53 (1921) give for the reaction $\text{N}_2\text{O}_5(\text{g}) \rightarrow \text{NO}(\text{g}) + \text{NO}_2(\text{g}) + \text{O}_2(\text{g})$ at 25°C the equilibrium constant $K = 5.15 \times 10^{-7} \text{ mole}^2 \text{ liter}^{-2} = 3.08 \times 10^{-4} \text{ atm}^2$. The resulting value of ΔH_f° 298.15 = 4.79 kcal. mole⁻¹ leads to $S_{298.15}^\circ = 82.8 \text{ cal. deg. mole}^{-1}$ for $\text{N}_2\text{O}_5(\text{g})$ when combined with the JANAF entropies and heats of formation of the components of the reaction.

The molecular structure is the nonplanar configuration derived from the electron diffraction study of Akinin, Vilkov and Resolovskii, Zhur. Strukt. Khim. 1, 1 (1960). A planar model (also point group C_{2v}) was assumed by Hasteau, Devlin and Wada, Spectrochim. Acta 18, 1641 (1962) in their approximate normal coordinate analysis of the infrared and Raman spectra. The frequency assignments of these authors are listed above in the order for the planar model, although the vibrations for the nonplanar form will separate differently into the species 5A₁, 3A₂, 3B₁ and 4B₂. Hasteau, et al., estimated the N-O-N deformation frequency (85 cm.⁻¹) from combination bands in the solid and gas phase spectra. The JANAF thermodynamic functions were obtained using these frequencies and assuming the two NO₂ groups to be hindered internal rotators. Barriers to internal rotation of 4.4 kcal. (corresponding to torsional vibrations of about 55 cm.⁻¹) were selected in order to give the observed entropy at room temperature. The principal moments of inertia for the nonplanar model were taken as $I_A = 30.60 \times 10^{-39}$, $I_B = 40.15 \times 10^{-39}$ and $I_C = 16.82 \times 10^{-39} \text{ g. cm.}^2$, while $I_A = 4.693 \times 10^{-39} \text{ g. cm.}^2$ was used for the reduced moment of inertia of the O₂ tops.

SILICON NITRIDE, ALPHA (α -Si₃N₄)

(CRYSTAL)

OPW = 140.2848

ΔHf° = Unknown

ΔHf°_{298.15} = -178 ± 7 kcal/mol

S°_{298.15} = [27 ± 4] gibbs/mol

T₀ = [2151]°K

Heat of Formation.

The equilibria (A) Si₃N₄(c) = 3 Si(l) + 2 N₂(g) and (B) Si₃N₄(c) = 3 Si(c) + 2 N₂(g) have been investigated by three groups. R. D. Pehlke and J. P. Elliott, Trans. Met. Soc. AIME 215, 781 (1959), made four series of measurements which mainly concerned reaction (A). W. B. Hinke and L. R. Banniley, J. Amer. Chem. Soc. 52, 48 (1930), made a single series of measurements which covered reactions (A) and (B). C. Matignon, Bull. Soc. Chim. France 13, 791 (1913), also gave a single equilibrium point for reaction (C) 3 SiO₂(c) + 6 C + 2 N₂ = Si₃N₄(c) + 6 CO(g). Below are shown 2nd and 3rd law analyses of the data. It should be noted that these analyses are based on the estimated heat capacities above 900°K, and on an estimated entropy. The uncertainty due to these estimates is estimated as ± 7 kcal in ΔHf°₂₉₈.

Reference	Points	Range °K	Reaction	2nd law ΔHf° ₂₉₈ kcal/mol	3rd law ΔHf° ₂₉₈ kcal/mol	Drift eu	*ΔHf° ₂₉₈ kcal/mol

					318.9		-175.1

*Calculated from the third law ΔHf°₂₉₈ values.

**Four points rejected due to failure of a statistical test; this set is a combination of the first four sets.

The adopted ΔHf°₂₉₈(α -Si₃N₄) = -178.7 kcal/mol.

L. A. McClaire and C. P. Coppel, A. D. Little, Inc., "Equilibrium Studies of Refractory Nitrides," Tech. Rept. APWL-TR-65-99, Part 11, Dec. 1966, have investigated the decomposition reaction(B). They conclude that at 1618°K the equilibrium pressure is roughly 0.15 mm. This corresponds to ΔHf°₂₉₈ = -182.3 kcal, and was not given any weight in the adopted value.

Heat Capacity and Entropy.

The enthalpy of α -Si₃N₄ has been measured at three temperatures, in the range 373° - 858°K, by S. Sato, Bull. Chem. Soc. Japan 13, 41 (1938). The heat capacity is calculated from the data assuming that a limit of 45 gibbs/mol is attained by 3000°K. The entropy is obtained from the equilibrium data of Pehlke and Elliott, loc. cit.

Decomposition Data.

The temperature of decomposition is calculated as the point at which the decomposition pressure of nitrogen reaches 1 atm.

TRIPHOSPHORUS PENTANITRIDE (P_3N_5)

(CRYSTAL)

GFW = 162.9549

$S^\circ_{298.15} = [44 \pm 6]$ gibbs/mol
Td = [730]°K
 $\Delta H^\circ_{298.15} = -64 \pm 5$ kcal/mol
 ΔH°_0 = Unknown

Heat of Formation.

The heat of formation is based on the work of A. Stock and P. Wrede, Chem. Ber. 40, 2923 (1907), who burned P_3N_5 in oxygen. They report a $\Delta H^\circ_{298} = -949.4$ kcal for the reaction $2 P_3N_5(c) + 7.5 O_2(g) = 1.5 P_4O_{10}(amorph) + 5 N_2(g)$. In NBS Technical Note 270-1, "Selected Values of Chemical Thermodynamic Properties," Washington, D.C. (1965), a value of -947.7 kcal is used for the above reaction and we adopt this value. Using the JANAF value for $P_4O_{10}(c)$ and correcting this to $P_4O_{10}(amorph)$ by adding -13.8 kcal/mol, from Technical Note 270-1, we obtain $\Delta H^\circ_{298} P_4O_{10}(amorph) = -716.5$ kcal/mol. Thus, we derive $\Delta H^\circ_{298} P_3N_5(c) = -63.525$ kcal/mol; however, because of the uncertainties in the heat of reaction and correction for amorphous P_4O_{10} we round the value to -64 ± 5 kcal/mol.

Heat Capacity and Entropy.

S. Sato, Sci. Papers Inst. Phys. Chem. Res. (Tokyo) 34, 584 (1958), gave an equation for the heat capacity in the range $273^\circ - 578^\circ K$. Judging from his results for $Be_3N_2(c)$ in the same paper, we believe his values will be slightly high at the upper end of the range. Thus, taking 8.2 gibbs/g-atom as the limiting value, a curve was drawn through Sato's values at the low end and approaching the limit asymptotically. The entropy was estimated from that of $Si_3N_4(c)$ by assuming that the ratio Op_{298}/S_{298} on a gram atom basis would be the same for $P_3N_5(c)$.

Temperature of Decomposition.

Td is calculated as the point at which the total pressure reaches 1 atm. This corresponds to $\log Kp = -0.76$ for the reaction $P_3N_5(c) = 0.75 P_4(g) + 2.5 N_2(g)$. The temperature of decomposition has been reported by V. F. Postnikov and L. L. Kuzmin, J. Appl. Chem. (USSR) 9, 429 (1955) as $1075^\circ K$. This has been confirmed by H. Moreau and P. Rocquet, Compt. Rend. 199, 1691 (1934) and Bull. Chim. France, 3, 1801 (1936); and E. O. Huffman, G. Tarbutton, G. V. Elmore, A. J. Smith and M. G. Rountree, J. Am. Chem. Soc. 79, 1765 (1957). However, it was also noted that $P_3N_5(c)$ is not reformed on cooling the decomposition products; thus the decomposition is non-equilibrium. It is known that the decomposition of AlN , BN and Be_3N_2 is kinetically limited and the equilibrium pressure is not attained until the average energy is greater than the activation energy. It appears that this is also the case for P_3N_5 and a high activation energy is expected.

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

D. L. Martin, Proc. Roy. Soc. A254, 433 (1960) reports that the low temperature heat capacity of sodium depends on the thermal history of the sample and ascribes this to a martensitic transformation. The effect is most pronounced in the range 40-80°K., where the graph of C_p against T increases continually for some samples and rises to a peak at 55°K. for others. Martin lists heat capacities obtained in several runs on "high purity" sodium at 21° to 300°K. and the higher values, those defining the peak at 55°K., have been selected here. The heat capacities reported by T. M. Dauphinee, D. L. Martin, and H. Preston-Thomas, Proc. Roy. Soc. A233, 214 (1955), have not been used, since one of the authors in a later publication (Martin, loc. cit.) questions the accuracy of the measurements above 100°K. and at lower temperatures there is no rise to a peak at 55°K. In the range 1.5° to 20°K., L. M. Roberts, Proc. Phys. Soc. B70, 744 (1957) and D. H. Parkinson and J. E. Quarrington Proc. Phys. Soc. A62, 762 (1955) have measured the heat capacity of very high purity sodium. The values of Parkinson and Quarrington are somewhat higher than those of Roberts and have been given greater weight, since they show better continuity with Martin's results. The results of G. L. Picard and P. E. Simon, Proc. Phys. Soc. B1, 1 (1948) have been rejected below 10°K., since they show a peak between 5° and 8°, a feature not verified by other workers; between 10° and 25°K. they agree exactly with the results of Parkinson and Quarrington. J. Rayne, Phys. Rev. 95, 1428 (1954) states that the graph of C_p against T has a small peak at about 0.9°K. This peak has not been observed in the work of W. H. Liden and N. E. Phillips, Phys. Rev. 118, 958 (1960) from 0.15° to 1°K. R. E. Gnaumer and C. V. Heer, Phys. Rev. 118, 955 (1960) from 0.4° to 2°K. and D. L. Martin, Phys. Rev. 124, 438 (1961) from 0.4 to 1.5°K.

T. B. Douglas, A. P. Ball, D. C. Ginnings, and W. D. Davis, J. Am. Chem. Soc. 74, 2472 (1952) report heat capacities in the range 273° to 1173°K. on a sample of not less than 99.9% purity. These values agree to within 1% with those of Martin in the range 273° to 300°K. and the two sets of data have been smoothly joined.

Melting.

Douglas et al. (loc. cit.) have determined the triple point to be $97.82 \pm 0.02^{\circ}\text{C.}$, from which the melting point is calculated to be $97.63 \pm 0.02^{\circ}\text{C.}$, and have measured the heat of fusion.

Heat of Sublimation.

At the boiling point and higher temperatures sodium vapor contains an appreciable proportion of diatomic molecules. G. W. Thompson and E. Garrels "Sodium - Its Manufacture, Properties and Uses," Ed. M. Sittig, Chapter 3, Reinhold Publishing Corporation, Inc., New York (1956), have made a careful analysis of the available vapor pressure data. Their results are consistent with the free energy functions calculated in the present work and have been adopted.

SODIUM (Na)

(LIQUID)

At. Wt. = 22.991

 ΔH_f^o 298.15 = 0.575 kcal. mole⁻¹ $S_{298.15}^o$ = 13.827 cal. deg.⁻¹ mole⁻¹ ΔH_m = 0.622 kcal. mole⁻¹ T_m = 370.98 ± 0.02°K T_b = 1156°K (Equilibrium mixture) T_b (Monatomic gas) = 1176.9°K ΔH_v 1176.9 = 23.285 kcal. mole⁻¹

Heat of Formation.

Obtained from the heat of fusion by adding $H_{370.98} - H_{298.15}$ for the solid and subtracting $H_{370.98} - H_{298.15}$ for the liquid.

Heat Capacity.

The heat capacity data of T. B. Douglas, A. F. Ball, D. C. Ginnings and W. D. Davis, J. Am. Chem. Soc. **74**, 2472 (1952) were used and were extrapolated below T_m and above 1173°K in a reasonable manner.

Entropy.

Back calculated from the entropy of the liquid at the melting point and the extrapolated heat capacity from the melting point to 298°K.

Vaporization.

Sodium vaporizes to a mixture of monatomic and diatomic gas. The total vapor pressure reaches 1 atm. at 1156°K. The vapor pressure of the monatomic gas reaches 1 atm. at 1176.9°K and the heat of vaporization to monatomic gas is 23.285 kcal. mole⁻¹ [See Na(crystal)].

Heat of Formation

The heat of formation at 0°K. was obtained from that of the ideal monatomic sodium gas by adding the enthalpy of ionization, calculated from the ionization limit given by C. E. Moore "Atomic Energy Levels" Natl. Bur. Standards Circ. 467 (1949). This was converted to 298°K. by using the formation equation Na(ref. state) - e⁻(ref. state) = Na⁺(monatomic gas), thus Na⁺ involves the difference in enthalpies of the two reference states as well as its own enthalpy.

Heat Capacity and Entropy

These were calculated using the electronic energy levels tabulated above, taken from C. E. Moore loc. cit.

Na⁺

Mar. 31, 1965

Ground State Configuration [$^2\Pi$]
 $S_{298.15}^\circ = [54.7 \pm 0.5] \text{ gibbs/mol}$
 $\Delta H_f^\circ = [20.3 \pm 10] \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = [20.0 \pm 10] \text{ kcal/mol}$

Electronic Levels and Quantum Heights

E_i , cm $^{-1}$	E_i	σ
0	[4]	$\sigma = 1$
$\omega_e X_e = [3.0] \text{ cm}^{-1}$		$r_e = [2.0] \text{ \AA}$
$\omega_e = [440] \text{ cm}^{-1}$		
$B_e = [0.4467] \text{ cm}^{-1}$		

Heat of Formation

Bawn and Evans (1) have studied the reaction rate of sodium vapor with nitrous oxide, nitrogen peroxide, nitromethane, ethyl nitrate and amyl nitrite, using the diffusion flame method. On the evidence of reaction rate measurements they estimated the value, $\Delta H_{298}^\circ < 0$, for the reaction $\text{Na(g)} + \text{NO(g)} = \text{NaO(g)} + \text{NO(g)}$. Based on this result, we calculate $\Delta H_{298}^\circ(\text{NaO, g}) > 12 \text{ kcal/mol}$, using $\Delta H_{298}^\circ = 25.8, 7.9$ and 21.6 kcal/mol for $\text{Na(g)}, \text{NO}_2(\text{g})$ and NO(g) , respectively.

Assuming that $D_0(\text{NaO}) = 1/2 D_0(\text{Na}_2) + D_0(\text{O}_2)$, or $\Delta H_0^\circ = 68.1 \text{ kcal/mol}$ for the reaction $\text{NaO(g)} = \text{Na(g)} + \text{O(g)}$, we derive $\Delta H_0^\circ = 16.7$ and $\Delta H_{298}^\circ = 16.4 \text{ kcal/mol}$, using $\Delta H_0^\circ = 25.8$ and 59.0 kcal/mol for Na(g) and O(g) , respectively. Somayajulu (2) found that in a sequence of similar diatomic molecules the force constant (k_e), dissociation energy (D_0) and equilibrium bond distance (r_e) are related by the expression $k_e r_e^3/D_0 = \text{constant}$. Using $r_e = 1.62 \text{ \AA}$, $D_0 = 77.9 \text{ kcal/mol}$ for LiO(g) , $r_e = 2.0 \text{ \AA}$ for NaO(g) and $k_e(\text{NaO})/k_e(\text{LiO}) = 0.4827$, we evaluate $D_0 = 65.4 \text{ kcal/mol}$ for NaO(g) , yielding $\Delta H_{298}^\circ(\text{NaO, g}) = 19.4 \text{ kcal/mol}$. The value k_e is calculated from the relation $k_e = 4\pi^2 \nu^2 \mu$ where ν is the vibrational frequency of the diatomic molecule and μ is the reduced mass.

The value of $\Delta H_{298}^\circ(\text{NaO, g})$ is tentatively adopted as $20 \pm 10 \text{ kcal/mol}$. The corresponding $D_0^\circ(\text{NaO})$ is $65 \pm 10 \text{ kcal/mol}$.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that for OH(g) which has the same number of valence electrons as NaO(g) . The values of ω_e and $\omega_e X_e$ are estimated by comparison with those for LiO(g) , LiF(g) and NaF(g) . The value of r_e is estimated from those for OH(g) , HF(g) and NaF(g) . B_e and a_e are derived from r_e , ω_e and $\omega_e X_e$ by the method suggested by Herzberg (3).

SODIUM MONOXIDE UNINEGATIVE ION (NaO⁻)

(IDEAL GAS)

GFW = 38.98975

Ground State Configuration [1²]ΔH_f^o = [-29 ± 20] kcal/molS_{298.15}^o = [52.0 ± 0.5] gibbs/molΔH_f^o_{298.15} = [-29 ± 20] kcal/mol

Electronic Levels and Quantum Weights

 $\frac{g_i}{\sum_i g_i} \frac{\text{cm}^{-1}}{0}$ $\omega_e X_e = [3.2] \text{ cm}^{-1}$
 $\omega_e = [0.00493] \text{ cm}^{-1}$
 $\sigma = 1$
 $r_e = [2.0] \text{ Å}$

Heat of Formation

The electron affinity (E. A.) of NaO⁻(g) is unavailable, therefore the value of ΔH_f^o(NaO⁻, g) is estimated. We first assume that the enthalpy change (ΔH_r^o) of the reaction (1) NaO⁻(g) = Na(g) + O⁻(g) is close to the average of the ΔH_r^o values for the reactions (2) NaO(g) = Na(g) + O(g) and (3) NaF(g) = Na(g) + F(g). The atom F(g) is isoelectronic with O⁻(g). In other words, the ΔH_r^o for reaction (1) is approximately 1/2(64.8 + 113.4) = 89.3 kcal/mol. Then we compare the ΔH_r^o values for the reactions (4) HO(g) = H(g) + O(g), (5) HO⁻(g) = H(g) + O⁻(g), and (6) HF(g) = H(g) + F(g), and find that ΔH_r^o for reaction (5) is experimentally determined as 109.7 kcal/mol which is about 8 kcal/mol more negative than the average of ΔH_r^o values for reactions (4) and (6). Based on this fact we estimate ΔH_r^o = 80 kcal/mol for reaction (1), yielding ΔH_f^o₂₉₈(NaO⁻, g) = -29 kcal/mol which is tentatively adopted. The uncertainty of this value may be ±20 kcal/mol. Based on this ΔH_f^o₂₉₈ value we calculate E. A. = 2.1 ± 0.9 eV for NaO(g). The corresponding value for HO(g) is 1.8 ± 0.1 eV.

Heat Capacity and Entropy

The ground state configuration is assumed to be the same as that of NaF(g) which is isoelectronic with NaO⁻(g). The values of ω_e, ω_eX_e and r_e are estimated by comparison with the observed data for NaF(g). The values of B_e and g_e are calculated from r_e, ω_e and ω_eX_e using the method recommended by G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950. The enthalpy at 0°K is -2.248 kcal/mol.

NaO₂SODIUM DIOXIDE (NaO₂)

MOL. WT. = 54.991

(CRYSTAL)

$$\Delta H_f^o = -63.1 \pm 0.7 \text{ kcal. mole}^{-1}$$
$$\Delta H_f^o 298.15 = -62.3 \pm 0.7 \text{ kcal. mole}^{-1}$$
$$\Delta H_f^o = 350 \text{ cal. mole}^{-1}$$
$$\Delta H_{t1}^o = 196.5^\circ \text{K.}$$
$$\Delta H_{t2}^o = 223.5^\circ \text{K.}$$
$$\Delta H_m^o = \text{Unknown}$$

Heat of Formation.

$\Delta H_f^o 298.15$ was obtained from National Bureau of Standards Report 7437, "Preliminary Report on the Thermodynamic Properties of Selected Light-Element and Some Related Compounds," January 1, 1962. P. W. Gilles and J. L. Margrave, J. Phys. Chem. 60, 1333 (1956) measured the heat of decomposition of NaO₂(c) in H₂O, yielding $\Delta H_f^o 298.15 = -62.1 \pm 0.7 \text{ kcal. mole}^{-1}$. From the original experimental data by R. de Forcrand, Compt. rend., 127, 514 (1898), 158, 843, 931 (1914), the value of $\Delta H_f^o 298.15$ was recalculated to be $-65.0 \text{ kcal. mole}^{-1}$ by P. W. Gilles and J. L. Margrave, loc. cit.

Heat Capacity and Entropy.

The low temperature heat capacities, $52.13^\circ \sim 296.46^\circ \text{K.}$, were measured by S. S. Todd, J. Am. Chem. Soc., 75, 1229 (1953). The heat capacities above 298.15°K. were estimated by comparison with those for Na₂O(c). $S_{298.15}$ was given by S. S. Todd, loc. cit., using $S_{51}^o(\text{extrap.}) = 2.23 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

T_{t1} , T_{t2} , ΔH_{t1}^o and ΔH_{t2}^o were calculated from the data reported by S. S. Todd, loc. cit.

Temperature of Melting.

The melting temperature was obtained from J. L. Margrave, private communication, May 21, 1963.

Heat of Formation

The enthalpy change of the reaction $\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(aq)$ has been determined by Matsui (1, 2), Roth (3, 4) and Rengade (5). Based on their reported ΔH_f° values, the corresponding ΔH_f° for $\text{Na}_2\text{O}(c)$ are calculated, using ΔH_f° for $\text{H}_2\text{O}(l)$ = -68.315 kcal/mol obtained from U. S. Natl. Bur. Std. Tech. Note 270-1, 1965, and ΔH_f° for NaOH derived from JANAF ΔH_f° (NaOH, c) and ΔH_{soln} and ΔH_{dil} reported by V. B. Parker, U. S. Natl. Bur. Std. NSRDS-NBS 2, 1965. The sample employed by Matsui was prepared by the method of Rengade (2) and contains $\text{Na}_2\text{O}_2(c)$ and $\text{Na}(c)$ as impurities. The sample used by Roth also contains 3.96 per cent (by weight) $\text{Na}_2\text{O}_2(c)$. Corrections in the reported results for such impurities have been made by the authors. However, in order to obtain better results, more measurements using purer samples are necessary. The enthalpy change of the reaction $2\text{Na}(c) + \text{H}_2\text{O}(l) = \text{Na}_2\text{O}(c) + \text{H}_2(g)$ was calculated by Rengade (5) from his measurements (5) incorporating with ΔH_f° = -86.2 kcal/mol for the reaction $2\text{Na}(c) + 2\text{H}_2\text{O}(l) = 2\text{NaOH}(aq) + \text{H}_2(g)$ determined by Joannis (6). The value ΔH_f° = -94.9 kcal/mol is derived from the data of Forcand (6) using ΔH_f° ($\text{Na}_2\text{O}_2, c$) = -122.66 kcal/mol. The results are presented in the table below.

Brewer (11) determined the equilibrium constants, 918-1467°K, for the vaporization of $\text{Na}_2\text{O}(c)$, using an effusion method. The Na_2O vapor consists predominately of $\text{Na}(g)$ and $\text{O}_2(g)$ molecules with any oxide molecules being not important. The Na/O ratio was not measured and assumed to be 2/1 in all calculations on Na_2O . Based on the reported data, we derive the equilibrium constants for the reaction $\text{Na}_2\text{O}(c) = 2\text{Na}(g) + 1/2\text{O}_2(g)$ and evaluate the third law ΔH_f° for $\text{Na}_2\text{O}(c)$. From this ΔH_f° value, we obtain ΔH_f° ($\text{Na}_2\text{O}, c$) = -65.6 ± 10 kcal/mol, employing ΔH_f° = 25.76 kcal/mol for $\text{Na}(g)$. The value -65.6 kcal/mol is not consistent with the other values determined above. This may be caused by an invalid assumption used in the calculation.

The heat of formation at 298°K for $\text{Na}_2\text{O}(c)$ is tentatively selected as -99.90 ± 1.0 kcal/mol.

Investigator	Reaction	ΔH_f° , kcal/mol	ΔH_f° , kcal/mol
1. Matsui (1929)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(7890 \text{ H}_2\text{O})$	-56.61 ± 0.16	-100.08
2. Matsui (1929)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(4600 \text{ H}_2\text{O})$	-56.70 ± 0.07	-99.89
3. Roth (1947)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(825 \text{ H}_2\text{O})$	-56.03 ± 0.13	-100.55
4. Roth (1948)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(825 \text{ H}_2\text{O})$	-55.98 ± 0.13	-100.60
5. Rengade (1907)	$\text{Na}_2\text{O}(c) + \text{H}_2\text{O}(l) = 2\text{NaOH}(aq)$	-56.50	-100.09
6. Forcand (1900)	$2\text{Na}(c) + \text{H}_2\text{O}(l) = \text{Na}_2\text{O}(c) + \text{H}_2(g)$	-28.70	-97.02
	$\text{Na}_2\text{O}(c) + 1/2\text{O}_2(g) = \text{Na}_2\text{O}_2(c)$	-27.76	-94.90

Heat Capacity and Entropy

The low temperature heat capacities, 15-380°K, were obtained from Furukawa (9). We make the corrections in the reported Cp values for impurity $\text{Na}_2\text{CO}_3(c)$ 2.33 per cent (by weight), analyzed by Grimley (10). The effect on heat capacity due to the presence of Na_2O_2 (0.91 per cent) impurity is insignificant. Using the smoothed low temperature Cp data the $S_{298.15}^\circ$ is calculated, based on $S_{15}^\circ = 0.0122 \text{ eu}$.

Grimley (10) measured the high temperature enthalpies, 380.1-1174.6°K, with a copper block drop-type calorimeter. The enthalpies for the γ phase, 380.1-980.4°K, are joined smoothly with the low temperature data and extrapolated to 1023.2°K (the $\gamma + \beta$ transition temperature). The enthalpies above 1023.2°K are obtained by extrapolation. The enthalpies measured at 1078.3 and 1174.6°K by Grimley are unreasonably large, and are not adopted.

Transition Data

The transition temperature and heats of transition were determined calorimetrically by Bouaziz (12) who used a very pure sample. The adopted $\Delta H^\circ = 0.42$ and 2.85 kcal/mol, are averages of the derived values, 0.36 - 0.48 and 2.7 - 3.0 kcal/mol, respectively.

Melting Data

T_m and ΔH_m° were obtained from Bouaziz (12). The adopted ΔH_m° is an average of the reported 10.8-12.0 kcal/mol. T_m has been reported as 1193 and 1190 ± 10°K by Bunzel (13) and Brewer (11), respectively, which are not adopted.

DISODIUM MONOXIDE (Na₂O)

(LIQUID)

GFW = 61.979

S_{298.15} = [21.895] gibbs/molΔH_{298.15}^a = [-89.112] kcal/mol

Tm = 1405.2°K

Td = 2223°K

Heat of Formation

The heat of formation is obtained from ΔH_{298.15}^a(c) by adding ΔH_m^a and the difference between H_{1405.2}^a - H₂₉₈^a for Na₂O(c) and Na₂O(l).

Heat Capacity and Entropy

The heat capacity is estimated by comparison with those for Na₂SiO₃(l) and SiO₂(l). The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

See the Na₂O(c) table.

Decomposition Temperature

Td is the temperature at which the Gibbs energy change of the decomposition reaction Na₂O(l) = 2Na(g) + 1/2O₂(g) approaches zero.

$$T_m = 1362 \pm 0.5^\circ\text{K}$$

Heat of Formation

The heats of solution of $\text{NaCl}(\text{c})$, $\text{Na}_2\text{SO}_4(\text{c})$, $\text{SiO}_2(\text{quartz})$, $\text{Na}_2\text{SiO}_3(\text{c})$, $\text{HCl}(\text{aq})$ and $\text{H}_2\text{SO}_4(\text{aq})$ in 20 percent hydrofluoric acid at -74.7°C were measured by F. C. Kraeck, Ann. Rept. of the Geophysical Laboratory, No. 1215, 69 (1953). The author derived two values of $\Delta H_{\text{sol}}(\text{c})$ of $\text{Na}_2\text{O}(\text{c})$ from those of $\text{NaCl}(\text{c})$, $\text{Na}_2\text{SO}_4(\text{c})$ and $\text{H}_2\text{SO}_4(\text{aq})$ presumably employing auxiliary data from U. S. Natl. Bur. Std. Circ. 500, 1952. We recalculate $\Delta H_{\text{sol}}(\text{c})$ of $\text{Na}_2\text{O}(\text{c})$ in the calorimetric solution as -87.50 (chloride scheme, originally -87.66) and -88.74 kcal/mol (sulfate scheme, originally -89.19), using recent $\Delta H_{\text{f}}^{298}$ values for $\text{NaCl}(\text{c})$, $\text{Na}_2\text{SO}_4(\text{c})$, $\text{HCl}(\text{aq})$, $\text{H}_2\text{SO}_4(\text{aq})$, and $\text{Na}_2\text{O}(\text{c})$. The corresponding enthalpy changes, $\Delta H_{\text{f}}^{298}$, for the reaction $\text{Na}_2\text{O}(\text{c}) + \text{SiO}_2(\text{quartz}) = \text{Na}_2\text{SiO}_3(\text{c})$ are derived as -55.20 and -56.38 kcal/mol. Adopting the weighted average $\Delta H_{\text{f}}^{298} = -55.59$ kcal/mol with $\Delta H_{\text{f}}^{298}(\text{Na}_2\text{O}, \text{c}) = -99.9$ kcal/mol and $\Delta H_{\text{f}}^{298}(\text{SiO}_2, \text{c}) = -217.7$ kcal/mol, we obtain $\Delta H_{\text{f}}^{298} = -373.19$ kcal/mol for $\text{Na}_2\text{SiO}_3(\text{c})$. This $\Delta H_{\text{f}}^{298}(\text{Na}_2\text{SiO}_3, \text{c})$ value is independent of future changes in $\Delta H_{\text{f}}^{298}$ of $\text{Na}_2\text{O}(\text{c})$ but the values of $\Delta H_{\text{sol}}(\text{c})$ are not independent. The adopted value of $\Delta H_{\text{f}}^{298}(\text{Na}_2\text{O}, \text{c})$ is the average of -100.1 and -99.7 kcal/mol reported by W. A. Roth and H. L. Kaula, Z. Anorg. Chem. 253, 352 (1947); ibid. 255, 329 (1949), and M. Matsui and S. Oka, J. Soc. Chem. (Japan) 32, 79 (1949), respectively.

W. A. Roth and H. Troitzsch, Z. Anorg. Chem. 260, 337 (1949), have measured the heats of solution of $\text{SiO}_2(\text{quartz})$, $\text{Na}_2\text{SiO}_3(\text{c})$ and $\text{Na}_2\text{O}(\text{c})$ in 10.3 percent HF at 22°C to be -32.85 , -67.96 and -88.9 kcal/mol, respectively. Using these results, we calculate the enthalpy change of the reaction $\text{Na}_2\text{O}(\text{c}) + \text{SiO}_2(\text{quartz}) = \text{Na}_2\text{SiO}_3(\text{c})$ as -53.79 kcal/mol and $\Delta H_{\text{f}}^{298}(\text{Na}_2\text{SiO}_3, \text{c}) = -371.39$ kcal/mol.

By use of high temperature reaction calorimetry D. C. Kroger and W. Janetzko, *Z. Anorg. Allgem. Chem.* **284**, 83 (1956), have determined the enthalpy change of the reaction $\text{Na}_2\text{O}_2(\text{c}) + \text{CO}_2(\text{g})$ as 17.99 kcal/mol. Based on $\Delta H_{298}^\circ = -270.26$, -582.92 and -94.05 kcal/mol for $\text{Na}_2\text{CO}_3(\text{c})$, $\text{Na}_2\text{Si}_2\text{O}_5(\text{gl})$ and $\text{CO}_2(\text{g})$, respectively, we evaluate $\Delta H_{298}^\circ = -370.57$ kcal/mol for $\text{Na}_2\text{SiO}_3(\text{c})$.

The heats of solution of $\text{Na}_2\text{CO}_3(\text{c})$, $\text{SiO}_2(\text{quartz})$ and $\text{Na}_2\text{SiO}_3(\text{c})$ in 39 percent HF at 26.5°C were measured to be -244.1 , -564.5 and -673.6 cal/g, by C. Hummel and H. E. Schwiete, *Glastech. Ber.* **32**, 327 (1959). From these results we calculate the enthalpy change to be 22.43 kcal/mol for the reaction $\text{Na}_2\text{CO}_3(\text{c}) + \text{SiO}_2(\text{quartz}) = \text{Na}_2\text{SiO}_3(\text{c}) + \text{CO}_2(\text{g})$, yielding $\Delta H_{298}^\circ(\text{Na}_2\text{SiO}_3, \text{c}) = -371.48$ kcal/mol.

Many other older calorimetric measurements have been made in order to derive the heat of formation for $\text{Na}_2\text{SiO}_2(\text{c})$, but most of these are of questionable accuracy and in some cases the products of the reaction are uncertain. For further details the review by N. W. McCready, *J. Phys. Colloid. Chem.* 52, 1277 (1948).

Heat Capacity and Entropy

The low temperature heat capacities, 53.6 – 294.5°K, were measured by K. K. Kelley, J. Am. Chem. Soc. **63**, 471 (1939), and high temperature enthalpies, 360.5 – 1749°K were determined by B. F. Naylor, J. Am. Chem. Soc. **67**, 466 (1945). The high temperature heat capacities are derived from the measured enthalpy data and joined smoothly with the low temperature Cp values. The entropy at 298°K is calculated using the adopted low temperature heat capacities, based on $S_{298}^{\circ} = 1.195$ eu.

Melting Data

See $\text{Na}_2\text{SiO}_3(l)$ table for details.

Heat of Formation

 $\Delta H_f^{298}(l)$ is obtained from $\Delta H_f^{298}(c)$ by adding ΔH_m^* and the difference between H_{1362}^* and H_{298}^* for crystal and liquid.

Heat Capacity and Entropy

The heat capacity above 900°K is derived as constant from the high temperature enthalpy data, 1414 - 1747°K, measured by B. F. Naylor, J. Am. Chem. Soc. 67, 466 (1945). A glass transition temperature is assumed at 900°K; i.e. the heat capacities below 900°K are taken to be the same as those for Na₂SiO₃(c).

The entropy is obtained in a manner analogous to that of the heat of formation. The low temperature heat capacities, 63.74 - 162.48°K, have been measured by V. V. Tarasov and Y. S. Savitskaya, Dokl. Akad. Nauk SSSR, 82, 1019 (1953); however, these are not adequate to be used to evaluate S_{298}^* .

Melting Data

The adopted $T_m = 1362^\circ K$, determined by F. C. Kracek, J. Phys. Chem. 24, 1583 (1930), is in good agreement with the value 1261°K reported by F. M. Jaeger, J. Wash. Acad. Sci., 1, 49 (1911), and later confirmed by G. W. Morey and N. L. Bowen, J. Phys. Chem. 28, 1167 (1924).

Other reported T_m values are 1280, 1291 and 1379°K by M. V. Kultascheff, Z. Anorg. Chem. 35, 186 (1903); R. C. Wallace, ibid., 53, 1 (1909); and H. S. van Klooster, ibid., 53, 135 (1910), respectively. These values are all lower than the adopted T_m value, probably because the sample compositions were not the exact composition of metasilicate.

The value of ΔH_m^* is evaluated from the adopted heat capacities for Na₂SiO₃(c) and Na₂SiO₃(l), and the enthalpy data reported by B. F. Naylor, loc. cit., assuming the final state of the calorimetric sample to be Na₂SiO₃(c). From the phase diagrams of Na₂SiO₃ with other compounds, K. K. Kelley, U. S. Bur. Mines Bull. 393, 1936, derived the values of ΔH_m^* of 9.8 - 10.5 kcal/mol.

SODIUM SULFATE, V (Na₂SO₄)

(CRYSTAL)

OPW = 142.0412

ΔHf° = -328.82 ± 0.2 kcal/mol
ΔHf°_{298.15} = -331.55 ± 0.2 kcal/mol
ΔHf°(V-I) = 2.584 kcal/mol

S°_{298.15} = 35.76 ± 0.1 gibbs/mol
π(V-I) = 521.7°K

Heat of Formation.

P. L. E. Shibata, S. Oda and S. Furukawa, J. Sci. Hiroshima Univ. (Japan) Ser. A, 3, 227 (1933), measured the emf of the cell: Na-amalg. (0.207%) | Na₂SO₄ (sat. soln.) | Hg₂SO₄ | Hg at 33-37°C. Extrapolating their results to 25°C, we obtain the ΔHf°_{298.15} = -153.77 kcal/mol for the reaction 2Na(c) + Hg₂SO₄(c) = 2Hg(l) + Na₂SO₄(c), which yields ΔHf°_{298.15} = -303.36 and ΔHf°_{298.15} = -331.53 kcal/mol for Na₂SO₄(c). The auxiliary value, ΔHf°_{298.15} = -149.59 kcal/mol, for Hg₂SO₄(c) is obtained from D. D. Wagman, W. H. Evans, I. Halow, V. B. Parker, S. M. Bailey and R. H. Schumm, "Selected Values of Chemical Thermodynamic Properties," Tech. Note 270-1, Natl. Bur. Std., Washington, D.C., 1965.

The heat of formation for Na₂SO₄(∞ H₂O) is evaluated as -332.10 kcal/mol, using ΔHf°_{298.15} = -57.39 and -217.32 kcal/mol for Na⁺(∞ H₂O) and SO₄²⁻(∞ H₂O), respectively, from Tech. Note 270-1, loc. cit. J.F. Coughlin, J. Am. Chem. Soc. 77, 868 (1955), determined the enthalpy change, ΔHf°_{298.15} = -0.301 ± 0.035 kcal/mol for the reaction Na₂SO₄(c, V) = Na₂SO₄(1050 H₂O). Adopting ΔHf°_{298.15} = 0.244 kcal/mol for the reaction Na₂SO₄(∞ H₂O) = Na₂SO₄ (1050 H₂O) from Natl. Bur. Std. Circ. 500, Washington, D.C., 1952, we derive the value, ΔHf°_{298.15} = 0.545 kcal/mol for the reaction Na₂SO₄(∞ H₂O) = Na₂SO₄(c, V), yielding ΔHf°_{298.15} = -331.56 kcal/mol for Na₂SO₄(c, V).

The heat of formation for Na₂SO₄(c, V) is adopted as -331.55 ± 0.2 kcal/mol.

Heat Capacity and Entropy.

The low temperature heat capacities, 13.74 - 313.44°K, have been measured by K. S. Pitzer and L. V. Coulter, J. Am. Chem. Soc. 60, 1310 (1938). The heat capacities in the temperature range 324.61 - 503.05°K were determined by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 5, 1321 (1961), using an adiabatic calorimeter. These two sets of data are joined smoothly and extrapolated graphically to 1500°K. The enthalpy values derived from the adopted Cp data are in fair agreement with those determined by J. P. Coughlin, J. Am. Chem. Soc. 77, 868 (1955). The corresponding Cp values, reported by M. M. Popov and G. L. Galchenko, J. Gen. Chem. USSR, 21, 2489 (1951), seem too high at the high temperature end. S_{298.15} is derived using the low temperature Cp data reported by K. S. Pitzer and L. V. Coulter, loc. cit., based on S°₁₄ = 0.057 eu.

Transition Data.

Polymorphism studies by P. C. Kracek, J. Phys. Chem. 33, 1281 (1929), and P. C. Kracek and R. E. Gibson, J. Phys. Chem. 33, 1304 (1929); ibid., 34, 148 (1930), indicate five distinct modifications, I-e, V, IV, III, II, I, of which only V and I are stable forms. Calorimetric studies of Shmidt and Sokolov, loc. cit., suggest another form, stable at high temperatures, which is labeled as δ.

The transition temperature and heat of transition are from the calorimetric data for thenardite reported by Shmidt and Sokolov, loc. cit.

GFw = 142.0412

(Crystal)

SODIUM SULFATE, III (Na₂SO₄)

(CRYSTAL)

GFw = 142.0412

$\Delta H_f^{\circ}{}_{298.15} = -331.005 \text{ kcal/mol}$
 $\Delta H_f^{\circ}(\text{III} \rightarrow \text{I}) = 1.630 \text{ kcal/mol}$

$S^{\circ}_{298.15} = 36.653 \text{ gibbs/mol}$
 $T_f(\text{III} \rightarrow \text{I}) = 521.7^{\circ}\text{K}$

Heat of Formation.

The $\Delta H_f^{\circ}{}_{298.15}(\text{Na}_2\text{SO}_4, \text{III})$ value is obtained from $\Delta H_f^{\circ}{}_{298.15}(\text{Na}_2\text{SO}_4, \text{I})$ by subtracting $\Delta H_t^{\circ}(\text{III} \rightarrow \text{I})$ and the difference between $H^{\circ}_{521.7} - H^{\circ}_{298.15}$ for $\text{Na}_2\text{SO}_4(\text{III})$ and $\text{Na}_2\text{SO}_4(\text{I})$.

J. P. Coughlin, J. Am. Chem. Soc. 77, 868 (1955), determined the heat of reaction of $\text{Na}_2\text{SO}_4(\text{V}) \rightarrow \text{Na}_2\text{SO}_4(\text{III})$ as $0.735 \pm 0.015 \text{ kcal/mol}$ at 303.16°K by solution calorimetry. This value is in reasonable agreement with 0.55 kcal/mol obtained from the selected heat of formation.

Heat Capacity and Entropy.

The heat capacities in the temperature range $319.02 - 521.65^{\circ}\text{K}$ were measured with an adiabatic calorimeter by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 6, 1321 (1961). The Cp values below 319°K and above 521°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data.

$\text{Na}_2\text{SO}_4(\text{III})$ is the melttable form obtained by cooling $\text{Na}_2\text{SO}_4(\text{I})$ in the absence of moisture. The temperature and heat of transition are taken from the calorimetric data of Shmidt and Sokolov, loc. cit. The value $\Delta H_t^{\circ}(\text{III} \rightarrow \text{I}) = 1.630 + 0.005 \text{ kcal/mol}$ is the average of three determinations.

J. P. Coughlin, loc. cit., reported the heat of transition $(\text{III} \rightarrow \text{I})$ at 514°K to be 1.680 kcal/mol , obtained by drop calorimetry, which is in good agreement with the value adopted.

Heat of Formation.

The $\Delta H_{298.15}^\circ(\text{Na}_2\text{SO}_4, \text{I})$ is obtained from $\Delta H_{298.15}^\circ(\text{Na}_2\text{SO}_4, \text{V})$ by adding $\Delta H^\circ(\text{V} \rightarrow \text{I})$ and the difference between $H_{521.7}^\circ - H_{298.15}^\circ$ for $\text{Na}_2\text{SO}_4(\text{V})$ and $\text{Na}_2\text{SO}_4(\text{I})$.

Heat Capacity and Entropy.

The heat capacities in the temperature range 538.65 - 917.65°K were measured with an adiabatic calorimeter by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. 8, 1321 (1961). The Cp values below 538.65°K and above 917.65°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data.

The value $\Delta H^\circ(\text{V} \rightarrow \text{I}) = 2.584 \pm 0.015 \text{ kcal/mol}$ is the average of two determinations from the calorimetric studies of Shmidt and Sokolov, loc. cit. The transition temperature was derived from the heating curve obtained in measuring the heat of transition. It was taken to be the temperature at which the specimen began to show its lowest heating rate. The heat of transition was the difference between the quantity of heat actually dissipated and the sum of the heats calculated from the heat capacity curve of the apparatus and from the specific heat curves of (V) and (I) linearly extrapolated to the transition temperature.

The values of T_t and ΔH° for $\text{Na}_2\text{SO}_4(\text{I}) \rightarrow \text{Na}_2\text{SO}_4(\delta)$ transition were reported by Shmidt and Sokolov, loc. cit. See $\text{Na}_2\text{SO}_4(\delta)$ table for details.

Melting Data.

See $\text{Na}_2\text{SO}_4(\text{I})$ table for details.

Sodium Sulfate, Delta (δ - Na₂SO₄)

GFW = 142.0412

(Crystal)

SODIUM SULFATE, δ (Na₂SO₄) (CRYSTAL) OFW = 142.0412

$$\Delta H_f^{298.15} = 37.741 \text{ gibbs/mol}$$

$$\Delta H_c^{298.15} = -330.083 \text{ kcal/mol}$$

$$\Delta H_c^{\circ} (I \rightarrow \delta) = 0.08 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 5.50 \text{ kcal/mol}$$

$$S_{298.15}^{\circ} = 37.741 \text{ gibbs/mol}$$

$$T_f (I \rightarrow \delta) = 980^{\circ}\text{K}$$

$$T_m = 1157^{\circ}\text{K}$$

Heat of Formation

The heat of formation ($\Delta H_f^{298.15}$) is obtained from $\Delta H_f^{298.15}$ for Na₂SO₄ (I) by adding $\Delta H_c^{\circ} (I \rightarrow \delta)$ and the difference between $H_{980} - H_{298.15}^{\circ}$ for Na₂SO₄ (I) and Na₂SO₄ (δ).

Heat Capacity and Entropy

The heat capacities in the temperature range 930 - 1010°K were measured by N. E. Shmidt and V. A. Sokolov, Russ. J. Inorg. Chem. **5**, 1321 (1961). The Cp values below 900°K are assumed to be the same as those for Na₂SO₄ (I). The heat capacities above 1010°K are obtained by graphical extrapolation. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

A small anomalous region between 690 - 720°C (965.15 - 993.15°K) on the Cp curve for Na₂SO₄ (c) was reported by N. E. Shmidt and V. A. Sokolov, loc. cit. By use of graphical integration of the area between the measured Cp curve and an arbitrary base line over the region 900 - 1100°K, a value of $\Delta H_c^{\circ} (I \rightarrow \delta) = 0.08 \text{ kcal/mol}$ was obtained. It is assumed to be 980°K. This anomalous region was first observed by G. W. Wyrouboff, Z. Krist. **21**, 284 (1933), and later confirmed by Y. F. Simanov and D. P. Kirikina, Zh. Neorg. Khim. **2**, 699 (1957), as a transition from a hexagonal to an orthorhombic structure. This transition was not observed by the earlier investigators because their measurements did not extend to that temperature range.

Melting Data

The temperature and heat of melting of Na₂SO₄ (I) \rightarrow Na₂SO₄ (l) were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ and liquid Na₂SO₄, we derive $H_m^{\circ} (\delta \rightarrow l) = 5.50 \text{ kcal/mol}$, using Coughlin's enthalpy data on Na₂SO₄ (l). The melting temperature is assumed to be the same as that reported by Coughlin.

T_m was reported to be 880°C (1153°K), 897°C (1170°K) and 888°C (1161°K) by Ruff and Plato, Ber. Deutsch. Chem. Ges. **36**, 2357 (1903); K. Hittner and O. Tammann, Z. Anorg. Chem. **43**, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. **50**, 355 (1906), respectively.

S_{298.15} = 42.777 gibbs/mol
Tm(δ → 1) = 1157°K

ΔHf°_{298.15} = -324.241 kcal/mol
ΔHm°(δ → 1) = 5.50 kcal/mol

Heat of Formation.
The value of ΔHf°_{298.15}(1) is obtained from ΔHf°_{298.15}(I) by adding ΔHm° and the difference between H°₁₁₅₇ - H°_{298.15} for Na₂SO₄(δ) and Na₂SO₄(I).

Heat Capacity and Entropy.
The enthalpies for Na₂SO₄(l) were measured by drop calorimetry in the temperature range 1157 - 1828°K by J. P. Coughlin, J. Am. Chem. Soc. **77**, 868 (1955); and in the temperature range 1173 - 1290°K by M. M. Popov and D. M. Ginzburg, J. Gen. Chem. USSR **25**, 1107 (1956). The constant heat capacity adopted here is derived from the enthalpy measurements reported by J. P. Coughlin, loc. cit. Below 800°K, the heat capacities are assumed to be the same as those of the δ phase. The entropy is calculated in a manner analogous to that of the heat of formation.

Melting Data.

The temperature and heat of melting of Na₂SO₄(I) → Na₂SO₄(l) were reported to be 1157°K and 5.67 kcal/mol, respectively, by Coughlin, loc. cit. No mention was made of the δ phase, and the enthalpy measurements were probably not sensitive enough to detect this phase. Based on our selected Cp values for δ liquid Na₂SO₄, we derive ΔHm°(δ → 1) = 5.50 kcal/mol, using Coughlin's enthalpy data on Na₂SO₄(l). The melting temperature is assumed to be the same as that reported by Coughlin.

Tm was reported to be 880°c(1153°K), 897°c(1170°K) and 888°c(1161°K) by Ruff and Plato, Ber. Deutch. Chem. Ges. **36**, 2357 (1903); K. Hüttner and G. Tammann, Z. Anorg. Chem. **43**, 215 (1905); and H. E. Boeke, Z. Anorg. Chem. **50**, 355 (1906), respectively.

SODIUM TUNGSTATE (Na_2WO_4) $\text{GFW} = 293.8272$

$\Delta H^*_{298} = -366.8 \pm 2 \text{ kcal/mol}$
 $\Delta H^*_{298,15} = -369.2 \pm 2 \text{ kcal/mol}$
 $\Delta H^*_{298} = 0.983 \text{ kcal/mol}$
 $\Delta H^*_{298} = 7.373 \text{ kcal/mol}$
 $\Delta H^*_{298} = 5.688 \text{ kcal/mol}$

Heat of Formation

The adopted heat of formation, $\Delta H^*_{298}(\text{Na}_2\text{WO}_4, \text{c}) = -369.2 \text{ kcal/mol}$, is calculated from $\Delta H^*_{298,15} = 19.44 \pm 0.08 \text{ kcal/mol}$ for the reaction $\text{H}_2\text{WO}_4(\text{c}) + 2\text{HCl}(\text{g}) = \text{Na}_2\text{WO}_4(\text{c}) + 2\text{HCl}(\text{g})$, using the JANAF value of $\Delta H^*_{298}(\text{H}_2\text{WO}_4, \text{c}) = -270.5 \text{ kcal/mol}$ and $\Delta H^*_{298}(\text{NaCl}, \text{c}) = -98.26 \text{ kcal/mol}$, and auxiliary data for $\text{HCl}(\text{aq})$ (11). The value of $\Delta H^*_{298,15}$ was determined by solution calorimetry by M. F. Kohler, L. B. Pankratz and R. Barany (1).

J. M. Sherfey and A. Brenner (2) measured by electrochemical calorimetry the heat of reaction $\Delta H^*_{298} = -7 \pm 1.5 \text{ kcal/mol}$ for $\text{W}(\text{c}) + \text{NaOH}(\text{ss}, 55\text{H}_2\text{O}) + 2\text{H}_2\text{O}(\text{l}) = \text{Na}_2\text{WO}_4(\text{c}) + 3\text{H}_2(\text{g})$. This value, combined with the heat of solution (Δ_{sol}), $\Delta H^*_{\text{sol}} = -1.7 \pm 0.1 \text{ kcal/mol}$ for $\text{Na}_2\text{WO}_4(\text{c}) = \text{Na}_2\text{WO}_4(\text{aq})$, gives $\Delta H^*_{298}(\text{Na}_2\text{WO}_4, \text{c}) = -368.4 \text{ kcal/mol}$, which is in good agreement with the value adopted.

The previously accepted value (Δ_{sol}), $\Delta H^*_{298}(\text{Na}_2\text{WO}_4, \text{c}) = -379 \pm 0.5 \text{ kcal/mol}$, was based on the unreliable $\Delta H^*_{298}(\text{H}_2\text{WO}_4, \text{c}) = -280.2 \pm 0.4 \text{ kcal/mol}$. (See JANAF $\text{H}_2\text{WO}_4(\text{c})$ table of March 31, 1967.) The other quoted value (1), $\Delta H^*_{298}(\text{Na}_2\text{WO}_4, \text{c}) = -385 \text{ kcal/mol}$, was obtained from W. G. Mixer's (3) measurement of the heat of reaction of tungsten powder with excess Na_2O_2 . This value was probably in error because the complex tungstate and peroxytungstates were formed in the reaction.

Heat Capacity and Entropy

Low temperature heat capacities ($52-299.87^\circ\text{K}$) were measured calorimetrically by E. G. King and W. W. Weller (4). The heat capacities above 300°K are estimated by extrapolation of the low temperature heat capacity curve to $C_{p,60} = 49.0 \text{ gibbs/mol}$. The latter is obtained from an estimate of C_p equal to 7 gibbs/g-atom at the first transition temperature.

The entropy, $S^*_{298} = 38.32 \pm 0.5 \text{ eu}$, is calculated from low temperature heat capacity data of King and Weller (4), based on an extrapolation of $S^*_{51} = 2.77 \pm 0.5 \text{ eu}$.

Transition Data

Transition temperatures and heats were obtained from differential heating and cooling curves both at atmospheric and higher pressures by R. W. Goranson and F. C. Kracek (7). Existence of three phases is confirmed by the earlier birefringence studies of H. E. Boeke (8).

R. Riccardi and C. Sinistri (10) found only one transition at 864°K with $\Delta H^* = 8.23 \text{ kcal/mol}$ by differential thermal analysis. This heat is apparently the sum of the two adopted heats of transition.

Melting Data

The adopted melting data were measured by the differential heating and cooling curve method by Goranson and Kracek (7). R. Riccardi and C. Sinistri (10) found the melting point at 971°K with $\Delta H^* = 7.52 \text{ kcal/mol}$ by differential thermal analysis.

SODIUM DISILICATE ($\text{Na}_2\text{Si}_2\text{O}_5$)

(CRYSTAL)

GFW = 182.1586

$S^0_{298,15} = 39.21 \pm 1.0$ gibbs/mol
 $T_f(B \rightarrow A\beta) = 951^\circ\text{K}$
 $T_f(A\beta \rightarrow A\alpha) = 980^\circ\text{K}$
 $T_m = 1147^\circ\text{K}$

Heat of Formation

The heats of solution of $\text{NaCl}(c)$, $\text{Na}_2\text{SO}_4(c)$, $\text{SiO}_2(\text{quartz})$, $\text{Na}_2\text{Si}_2\text{O}_5(c)$, $\text{HCl}(aq)$ and $\text{H}_2\text{SO}_4(aq)$, in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (3). The author derived two values of ΔH_{soln} of $\text{Na}_2\text{O}(c)$ from those of $\text{NaCl}(c)$, $\text{Na}_2\text{SO}_4(c)$, $\text{HCl}(aq)$ and $\text{H}_2\text{SO}_4(aq)$, presumably employing auxiliary data from (2). We recalculate ΔH_{soln} of $\text{Na}_2\text{O}(c)$ in the calorimetric solution as -87.50 (chlorine scheme originally -87.66) and -88.74 kcal/mol (sulfate scheme, originally -89.13), using recent $\Delta H^0_{f,298}$ values (15, 17, 18) for $\text{NaCl}(c)$, $\text{HCl}(aq)$, $\text{H}_2\text{SO}_4(aq)$, $\text{Na}_2\text{SO}_4(c)$, and $\text{Na}_2\text{O}(c)$. The corresponding enthalpy changes, $\Delta H^0_{f,298}$ for the reaction $\text{Na}_2\text{O}(c) + 2\text{SiO}_2(\text{quartz}) = \text{Na}_2\text{Si}_2\text{O}_5(c)$ are derived as -94.65 and -55.89 kcal/mol. Adopting the weighted average $\Delta H^0_{f,298} = -55.06$ kcal/mol with $\Delta H^0_{f,298}(\text{Na}_2\text{O}, c) = -99.9$ kcal/mol and $\Delta H^0_{f,298}(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta H^0_{f,298} = -590.36$ kcal/mol for $\text{Na}_2\text{Si}_2\text{O}_5(c)$. This $\Delta H^0_{f,298}$ ($\text{Na}_2\text{Si}_2\text{O}_5, c$) value is independent of future changes in $\Delta H^0_{f,298}$ of $\text{Na}_2\text{O}(c)$, but the values of ΔH_{soln} and $\Delta H^0_{f,298}$ are not independent.

Stevens et al. (3) measured the heats of solution of $\text{Na}_2\text{Si}_2\text{O}_5(c)$, $\text{Na}_2\text{O}(c)$ and $\text{SiO}_2(\text{quartz})$ in $\text{HF}(aq)$ at 25°C . Based on the reported results, the enthalpy change for the reaction $\text{Na}_2\text{O}(c) + 2\text{SiO}_2(\text{quartz}) = \text{Na}_2\text{Si}_2\text{O}_5(c)$ is calculated as -53.25 ± 0.32 kcal/mol, yielding $\Delta H^0_{f,298}(\text{Na}_2\text{Si}_2\text{O}_5, c) = -588.55$ kcal/mol.

Hummel (4) determined the heats of solution of $\text{Na}_2\text{Si}_2\text{O}_5(c)$, $\text{SiO}_2(\text{quartz})$ and $\text{Na}_2\text{CO}_3(c)$ in 39 percent HF at 26.5°C . From the data reported we derive the enthalpy change to be 70.88 kcal/mol for the reaction $\text{Na}_2\text{CO}_3(c) + 2\text{SiO}_2(\text{quartz}) = \text{Na}_2\text{Si}_2\text{O}_5(c) + \text{CO}_2(g)$. Employing $\Delta H^0_{f,298} = -270.26$, -217.7 and -94.05 kcal/mol for $\text{Na}_2\text{CO}_3(c)$, $\text{SiO}_2(\text{quartz})$ and $\text{CO}_2(g)$, respectively, we obtain $\Delta H^0_{f,298} = -590.73$ kcal/mol for $\text{Na}_2\text{Si}_2\text{O}_5(c)$ which is in good agreement with the adopted one.

Heat Capacity and Entropy

The low temperature heat capacities, $54.3 - 294.7^\circ\text{K}$, have been measured by Kelley (5) and the high temperature enthalpies, $376.8 - 1100.2^\circ\text{K}$, by Naylor (6). The derived high temperature heat capacities are joined smoothly with the low temperature ones at 298°K . An approximate C_p of 70 gibbs/mol is derived from the enthalpies above 980°K ; this value is extrapolated to 2000°K . The value of S^0_{298} is calculated from the adopted low temperature heat capacities based on $S^0_{298} = 2.945$ eu. The entropy extrapolation derives from the Debye-Einstein extrapolation of Kelley (5) which yields a C_p curve with an extra inflection in the region from 15 to 50°K . A more normal extrapolation would lead to a value of S^0_{298} which is lower by 0.5 eu.

There are six slowly inverting polymorphous phases (1, 2-9), namely A, B, C, D, E and F, of which only the first two phases are stable. Two rapid transitions have been reported at 951 and 980°K (1, 10). Phase A, which has two subphases, $A\alpha$ and $A\beta$, is stable above 951°K . The stable phase below 951°K is known as phase B, previously called $\beta\text{-Na}_2\text{Si}_2\text{O}_5$. The two values of $\Delta H^0_{f,298}$ derived from the enthalpy data of Naylor (6) using the adopted C_p values. Three more rapid transitions have been reported at 822 , 846 and 866°K (1, 10) in E, previously called $\gamma\text{-Na}_2\text{Si}_2\text{O}_5$. A recent examination of these transitions was reported by Willgallis and Range (10).

Transition Data

Melting Data

T_m is obtained from Morey (11). The selected value of ΔH^0_m is based on the following ΔH^0_m values derived from four different kinds of measurements.

Investigator	ΔH^0_m , kcal/mol ^a at 298°K	ΔH^0_m , kcal/mol ^a at 1147°K	Method ^b	Reference
Kelley (1936)	(7.51)	8.46	I	12
Kracek (1953)	5.25	(6.20)	II	1
Kröger-Janetzko (1956)	8.81	(9.76)	III	13
Kröger-Kreitlow (1956)	8.83	(9.78)	II	14
Schwiete-Ziegler (1958)	(7.50)	8.45	IV	15
Hummel-Schwiete (1959)	8.09	(9.04)	II	4

^aThe numbers in parentheses are derived from the measured ones at the other listed temperatures.

^bI = phase diagram; II = solution calorimetry; III = high temperature reaction calorimetry; and

IV = dynamic-differential calorimetric method.

SODIUM DISILICATE (Na₂Si₂O₅)

(LIQUID)

GFW = 182.1586

$S^{\circ}_{298.15} = 45.101$ gibbs/mol

$\Delta H^{\circ}_{298.15} = -582.811$ kcal/mol

$T_m = 1147^{\circ}\text{K}$

$\Delta H_m^{\circ} = 8.5$ kcal/mol

Heat of Formation

The $\Delta H^{\circ}_{298}(\ell)$ is obtained from $\Delta H^{\circ}_{298}(\text{c})$ by adding ΔH_m° and the difference between $H^{\circ}_{1147} - H^{\circ}_{298}$ for crystal and liquid. The heats of solution of NaCl(c), Na₂SO₄(c), H₂SO₄(aq), SiO₂(quartz) and Na₂Si₂O₅(gl) in 20 percent hydrofluoric acid at 74.7°C were measured by Kracek (1). Following the same procedure as described in the Na₂Si₂O₅(c) table, we derive the enthalpy changes, ΔH°_{298} , for the reaction Na₂O(c) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) as -48.40 and -50.64 kcal/mol using the heats of solution of Na₂O(c) as -87.50 (chloride scheme) and -88.74 kcal/mol (sulfate scheme), respectively. Adopting the weighted average $\Delta H^{\circ}_{298} = -49.81$ kcal/mol with $\Delta H^{\circ}_{298}(\text{Na}_2\text{O}, \text{c}) = -89.9$ kcal/mol and $\Delta H^{\circ}_{298}(\text{SiO}_2, \text{quartz}) = -217.7$ kcal/mol, we obtain $\Delta H^{\circ}_{298} = -585.113$ kcal/mol for Na₂Si₂O₅(gl).

Using high temperature reaction calorimetry, Kröger (2) determined the enthalpy changes as 25.28 ± 0.22 and -18.68 ± 0.36 kcal/mol for the reactions Na₂CO₃(c) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + CO₂(g) and 2NaOH(c) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + H₂O(l), respectively. From the given results, we calculate the corresponding values of $\Delta H^{\circ}_{298}(\text{Na}_2\text{Si}_2\text{O}_5, \text{gl})$ to be -586.32 and -589.46 kcal/mol, using $\Delta H^{\circ}_{298} = -270.26$, -217.70, -94.05, -101.90 and -68.32 kcal/mol for Na₂CO₃(c), SiO₂(quartz), CO₂(g), NaOH(c) and H₂O(l), respectively. These two $\Delta H^{\circ}_{298}(\text{Na}_2\text{Si}_2\text{O}_5, \ell)$ values, as well as the value -585.113 kcal/mol based on Kracek's data, are not adopted, because incorporating these $\Delta H^{\circ}_{298}(\text{gl})$ values with the value of $\Delta H^{\circ}_{298}(\text{c})$, gives values if the heat of melting at 298°K which are too low in comparison with the other values (see the Na₂Si₂O₅(c) table).

Hummel (3) measured the heats of solution of Na₂CO₃(c), SiO₂(quartz) and Na₂Si₂O₅(gl) in 39 percent hydrofluoric acid at 25.5°C, as -244.1, -584.5 and -573.7 cal/g, respectively. Based on these results, we derive the enthalpy change for the reaction Na₂CO₃(c) + 2SiO₂(quartz) = Na₂Si₂O₅(gl) + CO₂(g) to be 29.01 kcal/mol, yielding $\Delta H^{\circ}_{298}(\text{Na}_2\text{Si}_2\text{O}_5, \text{gl}) = -582.6$ kcal/mol which is in good agreement with the adopted value.

Heat Capacity and Entropy

Using drop calorimetry, Naylor (4) has measured the enthalpies of Na₂Si₂O₅(gl), 445.5 - 1120.7°K, and Na₂Si₂O₅(ℓ), 1173.2 - 1744°K. Based on the liquid enthalpy data, we evaluate the heat capacity of Na₂Si₂O₅(ℓ) to be 62.43 gibbs/mol. The Cp values below 1147°K are derived from the enthalpies measured at 445.5 - 1120.7°K by Naylor (4). Below 600°K, Cp is identical with that of the crystal. The adopted curve rises rapidly to a maximum in the glass transition region, 650-950°K, then smoothly approaches the value of the real liquid near Tm. The heat capacity of Na₂Si₂O₅(ℓ) is assumed to be constant in the temperature range 1147 to 2500°K.

S°_{298} is obtained in a manner analogous to that of the heat of formation.

Melting Data

See Na₂Si₂O₅(c) table for details.

Heat of Formation.

P. Brix and G. Herzberg, Can. J. Phys. 32, 110 (1954), observed 21 bands in the transition $X^3\Sigma^- \rightarrow B^3\Sigma^-$. The Birge-Sponer extrapolation to the dissociation products $3P_2 + 1D_2$ was corrected to the zero levels, $3P_2 + 5P_2$, to give the dissociation energy 41260 ± 15 cm.⁻¹. This is in agreement with the extrapolation of the band heads of the $X^3\Sigma^- \rightarrow A^3\Sigma^+$ transition which goes to the normal products. The extrapolation of the B level is very small, the lowest $\Delta G_{1/2}$ is 34 cm.⁻¹

Heat Capacity and Entropy.

The electronic levels from C. E. Moore, Nat. Bur. Standards, Circ. 467, (1949), were averaged above 80,000 cm.⁻¹

Heat of Formation.

The heat of formation was calculated from the equation: $O(g) + e^- \rightarrow O^-(g)$ with the JANAP auxiliary value for $O(g)$; using the measured electron affinity = 1.465 e.v. (33.783 kcal/mole) obtained from L. M. Branscomb, D. S. Burch, S. J. Smith and S. Guleman, Phys. Rev. **111**, 504 (1958). Other calculated values for the electron affinity are: 1.22 e.v. E. Clementi and A. D. McLean, Phys. Rev. **133**, 4419 (1964); 1.16 e.v. E. Clementi, A. D. McLean, D. L. Raimondi, and M. Yoshimine, Phys. Rev. **133**, A1274 (1964); and 1.47 e.v. B. Edlén, J. Chem. Phys. **33**, 98 (1960).

Heat Capacity and Entropy.

The electronic levels and quantum weights were estimated by assuming that the extra electron would produce an electronic structure similar to the next higher atomic numbered element, in this case F(I). An analogy was then made between O^- and F(I) with $O(I)$ and F(II), and $O(II)$ and F(III) in order to estimate the height of the first level above the ground state. The data for F(I), O(I), F(II), O(II) and F(III) were obtained from C. E. Moore, "Atomic Energy Levels", Vol. I, Circular of the National Bureau of Standards 467, June 15, 1949. It is possible that the entropy below 3000°K. could be in error by 0.5 e.v. due to the estimation of the low lying electronic level. The electronic levels above $1 \times 10^5 \text{ cm.}^{-1}$ were omitted because their contribution is negligible below 6000°K. The $H^\circ - H_{298}^\circ$ value at 0°K. is -1.567 kcal/mole.

Phosphorus Monoxide (P0)

Lead Monoxide, Red (PbO) (Crystal)

Mol. Wt. = 223.21

 ΔH_f^o 298.15 = -52.41 ± 0.16 kcal. mole⁻¹ $S_{298.15}^o$ = 15.6 ± 0.2 cal. deg.⁻¹ mole⁻¹ ΔH_f^o 298.15 = 63.88 ± 0.22 kcal. mole⁻¹ T_f = 762°K ΔH_f^o = 0.18 ± 0.23 kcal. mole⁻¹

Heat of Formation. Calculated from the cell reaction

reported by D. P. Smith and H. K. Woods, J. Am. Chem. Soc., 45, 2632 (1923), using ΔH_f^o 298.15 for $H_2O(l)$, -68.317 kcal. mole⁻¹, given by Natl. Bur. Standards Circular 500 (1952). ΔH_f^o values reported by other investigators were discussed by R. W. Millar, J. Am. Chem. Soc., 51, 207 (1929).

Heat Capacity and Entropy. Heat capacity values (51° to 298.15°K) were obtained from E. O. King, J. Am. Chem. Soc., 80, 2400 (1958).

For the higher temperature range, heat capacity given by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960) was used and joined smoothly to data of King at 298.15°K by graphical extrapolation. King obtained entropies below 51°K by empirical extrapolation of the heat capacity curve which fits the measured heat capacities within 1.3%.

Transition Data. Heat of transition recalculated from the data given by E. O. King, loc. cit.

Heat of Sublimation. Calculated from free-energy functions and vapor pressure reported by A. N. Nemeyanov, L. P. Firova and E. P. Isakova, Zhur. Fiz. Khim. 34, 1699 (1960) and R. H6rbe and O. Knacke, Z. Erzhbergbau u. Metallhutenw. 12, 321 (1959).

Lead Monoxide, Yellow (PbO) (Crystal)

Mol. Wt. = 223.21
 ΔH_f^o 298.15 = -52.07 ± 0.28 kcal. mole⁻¹
 $S_{298.15}^o$ = 16.1 ± 0.2 cal. deg⁻¹ mole⁻¹
 ΔH_s^o 298.15 = 63.54 ± 0.32 kcal. mole⁻¹
 T_m = 1170 ± 4°K.
 ΔH_m^o = 6.1 ± 0.1 kcal. mole⁻¹

Heat of Formation. Calculated from ΔH_f^o 298.15 for PbO (c, red) and ΔH_m^o 298.15 between PbO (c, red) and PbO (c, yellow).

Heat Capacity, Entropy, and Melting Data. C_p values (51° to 298.15°K.) obtained from E. G. King, J. Am. Chem. Soc., 80, 2400 (1958). For the higher temperature range, the heat capacity reported by E. N. Rodigina, K. Z. Gorn'skii and V. F. Luginina, Zhur. Fiz. Khim., 35, 1799 (1961) was used and joined smoothly to data of King at 298.15°K. by graphical extrapolation. T_m and ΔH_m^o given by E. N. Rodigina, K. Z. Gorn'skii and V. F. Luginina, loc. cit.

Heat of Sublimation. Calculated from ΔH_f^o 298.15 and ΔH_s^o 298.15 for PbO (c, red).

March 31, 1962

Lead Monoxide (PbO) (Liquid)

Mol. Wt. = 223.21
 $\Delta H_f^{\circ} 298.15 = [-46.712] \text{ kcal. mole}^{-1}$
 $S^{\circ} 298.15 = [20.546] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1170 \pm 4^{\circ}\text{K.}$
 $\Delta H_m^{\circ} = 6.1 \pm 0.1 \text{ kcal. mole}^{-1}$
 $T_b = 1789^{\circ}\text{K.}$
 $\Delta H_v^{\circ} = 49.53 \pm 0.22 \text{ kcal. mole}^{-1}$

Heat of Formation. Calculated from that of the crystal.

Heat Capacity, Entropy, and Melting Data. C_p , T_m , and ΔH_m° are obtained from E. N. Rodigina, K. Z. Gmel'skii and V. P. Luginina, Zhur. Fiz. Khim., **35**, 1799 (1961). The reported heat capacity is extrapolated to an assumed glass transition temperature of 780°K., below which the heat capacity is taken to be equal to that of the crystal, PbO (c, red).

Vaporization Phenomena. T_b and ΔH_v° calculated from $\Delta H_f^{\circ} 298.15$ for PbO (c, red) and functions for condensed and gaseous states.

SULFUR MONOXIDE (SO)

(IDEAL GAS)

MOL. WT. = 48.0634

Ground State Configuration $3 \sum^-$
 $S_{298.15} = 53.0 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H_f^0 = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 S_{298.15} = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{E_i \text{ cm.}^{-1}}{0} \frac{g_i}{3}$$

$\sigma = 1$
 $r_e = 1.481 \text{ \AA}$

$\omega_e = 1148.19 \text{ cm.}^{-1}$
 $\omega_e x_e = 6.116 \text{ cm.}^{-1}$
 $\alpha_e = 0.00562 \text{ cm.}^{-1}$

Heat of Formation

The dissociation energy of sulfur monoxide has been reported by following investigators:

D ₀ (SO) e.v.	(kcal. mole ⁻¹)	Investigator
5.053	(116.5)	E. V. Martin, Phys. Rev. 41 , 167 (1932).
5.184	(119.5)	A. O. Gaydon, "Dissociation Energies", Chapman & Hall Ltd. London, 1953.
4.001	(92.3)	G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Company, Inc. 2nd Ed., 1950.
5.357	(123.5)	R. G. W. Norrish and G. A. Oldershaw, Proc. Roy. Soc. A249 , 498 (1959).
5.510	(127.1)	J. J. McDermott, W. D. McGrath, Proc. Roy. Soc. A278 , 490 (1964).

E. V. Martin, loc. cit., has measured the spectrum of SO(g) in the region 2400-4000 Å, and both Herzberg's and Gaydon's data were based on Martin's spectroscopic measurement. Because of the ambiguity of defining the state of excitation of the atomic products resulting from predissociation, the dissociation energy of SO was in question. Herzberg favored D_0 (SO) = 92.3 kcal. mole⁻¹ but Gaydon D_0 (SO) = 119.5 kcal. mole⁻¹.

Norrish and Oldershaw, loc. cit., redetermined the absorption spectrum of SO by flash photolysis, and also corrected Martin's original vibrational numbering, and then obtained the dissociation energy, D_0 (SO) = 123.5 kcal. mole⁻¹, based on the assumption of predissociation into S(¹D) and O(¹P). This value, D_0 = 123.5 kcal. mole⁻¹, has been selected as the dissociation energy for SO(g) and combination with JANAF values of ΔH_f^0 (S; g) and ΔH_f^0 (O; g) gives the heat of formation of sulfur monoxide, $\Delta H_f^0 S_{298} = 1.64 \pm 0.3 \text{ kcal. mole}^{-1}$, which is adopted in this tabulation.

R. Colby, P. Goldfinger and M. Jeunehomme, Trans. Faraday Soc. **60**, 306 (1964), have confirmed the selected D_0 (SO) = 123.5 kcal. mole⁻¹ in their mass spectrometric studies on the vaporization of CsS, SFS and BS. J. J. McDermott and W. D. McGrath, loc. cit., reported the dissociation energy to be 127.1 kcal. mole⁻¹ based on their ultraviolet spectroscopic studies. This value appears to be the D_0 from the minimum of the potential curve which corresponds to D_0 (SO) = 125 ± 1.5 kcal. mole⁻¹.

Besides the spectroscopic information, G. St. Pierre and J. Chipman, J. Am. Chem. Soc. **76**, 4787 (1954), have reported $\Delta H_f^0 S_{298} = -19 \text{ kcal. mole}^{-1}$ for the reaction $0.5 S_2(g) + 0.5 O_2(g) \rightarrow SO(g)$ in the equilibrium study of lime-iron oxide slags with SO₂ or SO₂-CO mixtures. Using $\Delta H_f^0 S_{298} (S_2f, g) = 30.8 \text{ kcal. mole}^{-1}$, the derived heat of formation, $\Delta H_f^0 S_{298} (SO, g) = -3.6 \text{ kcal. mole}^{-1}$ was obtained. However, this value is doubtful because the reported $\Delta H_f^0 S_{298} = -19 \text{ kcal. mole}^{-1}$ was dependent upon many assumptions and subsidiary data. E. W. Dewing and P. D. Richardson, Trans. Faraday Soc. **54**, 675(1958) have measured the equilibrium constants for the reaction $S_2(g) + 2SO(g) \rightarrow 4SO(g)$ at 1250°C. and $SO_2(g) \rightarrow SO(g) + 1/2 O_2(g)$ at 1500°C. Using the JANAF auxiliary data, the former yields $\Delta H_f^0 S_{298} (SO, g) = -19 \text{ kcal. mole}^{-1}$ and the latter -0.17 kcal. mole⁻¹, respectively. The average of these two values is $\Delta H_f^0 S_{298} = 0 \text{ kcal. mole}^{-1}$. Although D. Meschi and R. Myers, J. Mol. Spectry. **3**, 405 (1959) and U. Blukis and R. Myers, J. Phys. Chem. **69**, 1154 (1965), have certainly concluded in their microwave spectroscopic studies that the SO₂ species was one of the important products in the Sulfur - SO₂ equilibrium which was considered as unimportant by Dewing and Richardson, the value, $\Delta H_f^0 S_{298} (SO, g) = 0 \text{ kcal. mole}^{-1}$, derived from Dewing and Richardson is still very close to the selected value, $\Delta H_f^0 S_{298} (SO, g) = 1.64 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy

The molecular constants ω_e , $\omega_e x_e$ and α_e were obtained from R. Norrish and G. Oldershaw, loc. cit., and the values of r_e and B_e were recently measured in the microwave spectrum by P. X. Powell and D. R. Lide, Jr., J. Chem. Phys. **41**, 1413 (1964).

DISULFUR MONOXIDE (S₂O)

MOL. WT. = 80.1274

(IDEAL GAS)

Point Group C_{2v}
 $\Delta H_f^0 = 63.8 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $\Delta H_f^0 = [-13.5 \pm 8] \text{ kcal. mole}^{-1}$
 $\Delta H_f^0 = 298.15 = [-13.5 \pm 8] \text{ kcal. mole}^{-1}$

Ground State Quantum Weight = 1
 Vibrational Frequencies and Degeneracies
 $\nu, \text{ cm.}^{-1}$

679 (1)
 388 (1)
 1165 (1)

Bond Distance: S-S = 1.884 Å S-O = 1.465 Å
 Bond Angle: S-S-O = 118°
 Product of the Moment of Inertia: $I_A I_B I_C = 6.2741 \times 10^{-115} \text{ g. cm.}^2$

Heat of Formation.

There is no direct measurement of the standard enthalpy of formation for S₂O(g). U. Blukis and R. Myers, J. Phys. Chem., **69**, 1154 (1965), have discussed the discrepancy of the values of ΔH_f^0 which vary from -1 to -35 kcal. mole⁻¹. R. Hagemann, Compt. Rend., **225**, 1102 (1962), reported ΔH_f^0 = -17 kcal. mole⁻¹ from his ionization and appearance potential measurements by mass spectrometry. R. Steudel and P. W. Schenk, Z. Physik Chem., **43**, 33 (1964), estimated the enthalpy of formation as -22.7 kcal. mole⁻¹. If the bond dissociation energies D(S-O) = 123.5 kcal. mole⁻¹ and D(S-S) = 101 kcal. mole⁻¹ were used to estimate the dissociation energy of S₂O (i.e. D(S₂O) = 224.5 kcal. mole⁻¹), one will obtain ΔH_f^0 = -35.5 kcal. mole⁻¹. A. V. Jones, J. Chem. Phys., **18**, 1263 (1950), reported the predissociation energy, 91 kcal. mole⁻¹, for sulfur monoxide from the infrared and ultraviolet spectra. [D. Meschi and R. Myers, J. Mol. Spectro., **3**, 405 (1959), have concluded from their experiment that the so called sulfur monoxide is S₂O.] Therefore, if 30(g) + S(g), were the dissociation products, the ΔH_f^0 would be -25.4 kcal. mole⁻¹; and if S₂(g) + O(g) were the products, the ΔH_f^0 would be -1.2 kcal. mole⁻¹. (All JANAP auxiliary data used in calculation.)

E. Dewing and F. Richardson, Trans. Faraday Soc., **54**, 679 (1958), have investigated the gas phase equilibria in the sulfur-oxygen vapor at 1250° and 1500°C respectively. U. Blukis and R. Myers (loc. cit.) recalculated their data based on the assumption that the S₂O (instead of SO) was the major product in the equilibrium, and obtained ΔH_f^0 = -13 kcal. mole⁻¹ for S₂O(g) which is adopted in this table.

Heat Capacity and Entropy.

The bond distance, angle, and vibrational frequencies were obtained from the microwave and infrared spectra measurements by D. Meschi and R. Myers, loc. cit., and U. Blukis and R. Myers, loc. cit. The three principal moments of inertia are $I_A = 2.0219 \times 10^{-39}$, $I_B = 16.6342 \times 10^{-39}$ and $I_C = 18.6580 \times 10^{-39} \text{ g. cm.}^2$

Ground State Configuration $1s^2$
 $S_{298.15}^\circ = 50.54 \text{ gibbs/mol}$
 $\Delta H_f^\circ = -24.3 \pm 2 \text{ kcal/mol}$
 $\Delta H_f^\circ = -24 \pm 2 \text{ kcal/mol}$

Heat of Formation

The adopted value is based on equilibrium data summarized below. The more reliable results from three different reactions lie in the range from about -23 to -26 kcal/mol. Extreme values, including -20 and -32 kcal/mol, can be discounted on experimental grounds. Margrave (1) recently reported $\Delta H_f^\circ = 82.8 \pm 1.5 \text{ kcal/mol}$ for $0.5510_2(\text{g}) + 0.5510_2(\text{g}) = \text{SiO}(\text{g})$, but details are not yet available. Assuming that this corresponds to reaction A below, we calculate $\Delta H_f^\circ = -25.4 \text{ kcal/mol}$. Reaction A involves the nominal composition $\text{SiO}(\text{s})$ which is treated as an intimate mixture of $0.5510_2(\text{c}) + 0.5510_2(\text{high cristobalite})$. X-ray studies (13, 14) suggest that the condensed "SiO" used in (1, 2) is probably a mixture of Si and amorphous or vitreous SiO_2 . The adopted ΔH_f° corresponds to $D_0^\circ = 190 \pm 3 \text{ kcal/mol}$. This may be compared with $D_0^\circ = 179 \text{ kcal/mol}$ obtained by linear Birge-Sponer extrapolation of the ground state vibrational constants and with $D_0^\circ = 185 \pm 7 \text{ kcal/mol}$ obtained by Barrow (15) from $D_0^\circ(\text{LiX}) = 77.5 \text{ kcal/mol}$ for the excited state at 5280 cm^{-1} . Barrow assumed $D_0^\circ/D_0^\circ(\text{LiX}) = 0.456$ based on related molecules.

Heat Capacity and Entropy

All constants for the ground state and the A¹Π state at 42640 cm⁻¹ are taken from the analysis of the A-X system reported by Lagerqvist (16). An intercombination transition has been observed and assigned as $1s^2 3^1\Pi$ by Verma (17). The value of the a-X excitation energy is unknown but is estimated here as 30000 ± 5000 cm⁻¹ by comparison with the A and A states of CO and A¹CL. Several additional excited states are known (18, 19) to lie near or above the A state, but they are omitted because their contribution to the thermal functions is negligible.

Heat of Formation.

G. L. Humphrey, *J. Am. Chem. Soc.* **73**, 1587 (1951), determined the heat of combustion $\Delta H_{298}^\circ = -101.61 \pm 0.12$ kcal/mol for the reaction $\text{TiO}(\alpha) + 1/2\text{O}_2(g) = \text{TiO}_2(\text{rutile})$. Based on this result and on $\Delta H_{298}^\circ(\text{rutile}) = -225.8 \pm 1$ kcal/mol, the adopted $\Delta H_f^{298}^\circ$ for $\text{TiO}(\alpha)$ is calculated to be -124.19 ± 1 kcal/mol. A value of -125.4 ± 0.4 kcal/mol was reported by S. M. Ariya, M. P. Morozova and E. Vol'f, *Russ. J. Inorg. Chem. (English Transl.)* **2**, 16 (1957), who measured the heats of combustion of various compositions in the Ti-O system. Ariya et al. used an estimated correction for the formation of $\text{TiO}_2 \cdot x$, while Humphrey obtained values of $0.2 - 0.4$ kcal/mol by grinding the product and returning it with white oil. Most of the assigned uncertainty arises from this problem of non-stoichiometry [see $\text{TiO}_2(\text{rutile})$ for further details].

Heat Capacity and Entropy.

The low temperature heat capacities, $52.6 - 296.3^\circ \text{K}$, were measured by C. H. Shomate, *J. Am. Chem. Soc.* **68**, 310 (1946). The high temperature enthalpies, $357.0 - 1771^\circ \text{K}$, were determined by B. F. Naylor, *J. Am. Chem. Soc.* **69**, 1077 (1946), by use of drop calorimetry. The high temperature Cp's, $357 - 1200.5^\circ \text{K}$, derived from the enthalpy data, are joined smoothly with the low temperature heat capacities at 298°K . The Cp values above 1200°K are obtained by extrapolation. The entropy is obtained from Cp* using $S_{50}^\circ = 4.13$ eu; this extrapolation includes $0.23, 1.7$ and 2.2 eu for contributions of the lattice, of vacancies and of spin magnetic effects, respectively.

P. W. Dilles, *J. Chem. Phys.* (in press), discussed the inconsistencies in the thermodynamic properties of TiO as derived from widely different measurements. These inconsistencies include (1) a difference of 10 kcal/mol in H_f° values for $\text{TiO}(g)$ obtained from vaporization of TiO and $\text{Ti}_2\text{O}_3(2)$ a difference of about 10 kcal/mol between the calorimetric data for $\text{TiO}(g)$ and a recent re-assessment of the partial free energy of dissociation for the TiO system, and (3) ent. data which suggest that the entropy of $\text{TiO}(g)$ should be increased relative to those of Ti and Ti_2O_3 . In order to minimize these discrepancies, we tentatively increase the experimental value of S_{298}° by addition of estimated contributions due to vacancies in the crystal lattice and to spin-magnetic effects of Ti^{2+} ion.

P. Enrich, *Z. Elektrochem.* **45**, 362 (1959) and Z. Anorg. Chem. **247**, 53 (1941), concluded from the difference in pycnometric and X-ray densities of $\text{TiO}(g)$ that about 25 percent of the Ti and O lattice sites are vacant. This was confirmed later by S. Anderson, B. Gollen, U. Kuylenstierna and A. Magneli, *Acta Chem. Scand.* **11**, 1641 (1957), A. D. Pearson, *J. Phys. Chem. Solids* **5**, 316 (1958), and M. E. Straumanis and H. W. Li, *Z. Anorg. Allgem. Chem.* **305**, 143 (1960). Anderson et al. noted that there may be a "close structural kinship" between the α and β forms, based on the similarity of their densities and the pronounced relationship between their powder diffraction patterns. The authors suggested that the (presumably) random vacancies in $\text{TiO}(g)$ may occur in an ordered way in $\text{TiO}(\alpha)$. Recent electron diffraction studies by J. M. Cowley, *Acta Cryst.* (to be published), may provide an answer to this problem. Assuming the vacancies to be randomly arranged, we estimate the residual entropy of $\text{TiO}(g)$ due to vacancies as $-2R(0.85 \ln 0.85 + 0.15 \ln 0.15) = 1.7$ eu, based on the method proposed by M. Hoch, A. S. Iyer and J. Neiken, *J. Phys. Chem. Solids* **23**, 1463 (1962). An alternative possibility for increasing the entropy of $\text{TiO}(g)$ is discussed in the Transition Data section of the table for $\text{TiO}(g)$.

Metallic-type conductivity of $\text{TiO}(\alpha)$ at temperatures $80 - 1000^\circ \text{K}$ was reported by A. D. Pearson, loc. cit., and P. J. Morin, *Phys. Rev. Letters* **3**, 34 (1959). This led J. B. Goodenough, *Phys. Rev.* **117**, 1442 (1960), to suggest the existence of strong cation-anion interactions and the possibility of a low temperature transformation of the martensitic or antiferromagnetic type. Goodenough noted that the isolectric compound VN becomes superconducting below 8.2°K . We approximate the entropy contribution of these various possibilities at 50°K by a spin-magnetic term of $\text{Rln}3 = 2.2$ eu.

Transition Data.

See $\text{TiO}(g)$ table.

Heat of Sublimation.

The difference between $\Delta H_f^{298}^\circ$ for $\text{TiO}(g)$ and $\text{TiO}(\alpha)$ is ΔH_{298}° .

Mar. 31, 1967

TITANIUM MONOXIDE, BETA (β -TiO) (CRYSTAL) OPW = 63.8994

S₂₉₈^o.15 = [12.372] gbbu/mol $\Delta H^{\circ}_{298.15} = [-123.872]$ kcal/mol

Tt = 1264°K $\Delta H^{\circ} = 0.85$ kcal/mol

Tm = 2023°K $\Delta H^{\circ} = [13]$ kcal/mol

Heat of Formation.

The $\Delta H^{\circ}_{298}(\beta)$ is obtained from $\Delta H^{\circ}_{298}(\alpha)$ by adding ΔH° and the difference between H₁₂₆₄ - H₂₉₈ for TiO(α) and TiO(β).

Heat Capacity and Entropy.

High temperature enthalpies, 1273 - 1771°K, have been measured with a drop calorimeter by B. P. Naylor, J. Am. Chem. Soc. 88, 1077 (1946). The adopted heat capacities are derived from these data, assuming the final state to be TiO(α). This problem is discussed in the Transition Data section. Cp values below 900°K are assumed to be the same as those for TiO(α). The heat capacities at temperatures 900 - 1273°K and above 1771°K are obtained by extrapolation.

The S₂₉₈^o is derived in a manner analogous to that of the heat of formation.

Transition Data.

Tt and ΔH° are derived from the enthalpy data of Naylor, loc. cit., assuming that TiO(α) is the final state of the drop experiment. The X-ray studies of C. C. Wang and N. J. Grant, J. Metals 5, 184 (1956), and A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), appear to contradict this assumption. These authors found that the α form of stoichiometric TiO was obtained at room temperature only by annealing the β phase for long periods below 1223°K. Samples quenched from temperatures of 1223°K or higher retained the NaCl structure of the β form. Since the drop calorimetric experiment is similar to quenching, it is possible that the final state was mostly the β form. If this is the case, then the derived values of ΔH° and ΔS° are probably much too small. This would be an alternative means for increasing the entropy of TiO(β). It is possible, however, that differences in particle size allowed Naylor's sample to drop to the α form, or that the β form was stabilized by impurities in the X-ray studies. Further experiments are desirable in order to resolve this question. Also related to the question is the fact that the structure of TiO(α) has not been reported, probably because the X-ray diffraction pattern is quite complex.

F. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), reviewed the phase data and presented the most current phase diagram for the Ti-O system. This diagram suggests that stoichiometric TiO(α) starts to transform near 1210°K with formation of the two phases TiO_{1+x}(β) and Ti₂O. Transformation to stoichiometric TiO(β) is complete near 1270°K, which is essentially the Tt chosen by Naylor. This behavior is consistent with Naylor's observation of "pre-transition effects" in the enthalpy between 1224 and 1264°K.

Melting Data.

See TiO(1) table for details.

TITANIUM MONOXIDE (TiO)

(LIQUID)

OPW = 63.8994

 $\Delta H_f^{298.15} = [-112.801] \text{ kcal/mol}$ $\Delta H_m^{\circ} = [13] \text{ kcal/mol}$ $\Delta H_v^{\circ} = [91.6] \text{ kcal/mol}$ $S_{298.15}^{\circ} = [14.235] \text{ gibbs/mol}$ $T_m = 2023^{\circ}\text{K}$ $T_b = [3934] ^{\circ}\text{K}$

Heat of Formation.

The value of ΔH_f^{298} for TiO(l) is obtained from that of TiO(s) by adding ΔH_m° and the difference between $H_{2023}^{\circ} - H_{298}^{\circ}$ for TiO(s) and TiO(l).

Heat Capacity and Entropy.

The heat capacity for TiO(l) is estimated on the basis of 8 cal/g-atom. S_{298}° is obtained in a manner analogous to that of the heat of formation.

Melting Data.

T_m is taken from W. Dawid and K. Schröter, Z. Anorg. Allgem. Chem. 253, 178 (1957). The heat of melting is estimated by comparison with that of VO(c) reported by C. E. Wicks and P. E. Block, U. S. Bur. Mines Bull. 605, 1963.

T_b has also been reported as 2023 and 2103°K by H. Nishimura and H. Kimura, J. Japan Inst. Metals (Sendai) 20, 589 (1956), and R. DeVries, R. Roy, and E. Osborne, Trans. Brit. Ceram. Soc. 53, 525 (1954), respectively. According to the Ti-O phase diagram reported by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. 49, 180 (1966), TiO melts incongruently.

Vaporization Data.

T_b is calculated as the temperature at which the Gibbs energy change of the reaction TiO(l) = TiO(g) approaches zero. The difference between ΔH_f° for TiO(g) and TiO(l) at T_b is ΔH_v° .

Heat of Formation

P. W. Gilles, J. Chem. Phys. (to be published), has discussed the difference of about 10 kcal/mol in the dissociation energies of TiO(g) obtained from vaporization of $\text{Ti}_2\text{O}_3(\text{s})$ and TiO(p). By mass spectrometric and Knudsen effusion techniques, P. O. Wahlbeck and P. W. Gilles, J. Chem. Phys. 45, 2465 (1967), studied congruently vaporizing $\text{Ti}_2\text{O}_3(\text{s})$ and derived $D^\circ(\text{TiO}, \text{g}) = 7.26 \pm 0.10 \text{ eV}$. Values of 6.88, 6.93 and 6.8 eV were derived from incongruently vaporizing TiO(p) in earlier studies reported by Q. D. Wheatley, Ph. D. Thesis, University of Kansas, 1964; W. O. Groves, M. Hoch, and H. L. Johnston, J. Phys. Chem. 59, 127 (1955); and J. Berkowitz, W. A. Chupke, and M. O. Inghram, J. Phys. Chem. 61, 1569 (1957). A spectroscopic value of 6.8 eV is obtained by Birge-Sponer extrapolation of the vibrational constants given on this table. Related discrepancies are listed in the Heat Capacity and Entropy section of the table for TiO(c). O. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Co., Inc., New York, 1950, reported $D^\circ = 6.9 \text{ eV}$.

In order to minimize these discrepancies, we tentatively increase the entropy of TiO(c) [see TiO(c) table for details] and re-evaluate the vapor pressure data by the second and third law methods. The results are given in the table below. Values derived from TiO(p) are uncertain due to excess oxygen in the condensed phase; e.g., the sample of Groves et al. contained an excess of about 3%. Our analysis assumes that the activity of TiO is unity in the actual condensed phase. The value of $\Delta H_{298}^\circ(\text{TiO}, \text{g})$ adopted is $3.75 \pm 5 \text{ kcal/mol}$.

Heat Capacity and Entropy

The electronic spectrum of TiO(g) consists of both singlet and triplet systems with near-degenerate low-lying states. The lowest-lying triplet was originally thought to be $^3\Pi$ by Herzberg, loc. cit., B. Rosen, "Selected Constants," Hermann & Co., Paris, 1951, and J. O. Phillips, J. Astrophys. 115, 567 (1952); *ibid.*, 119, 274 (1954), but has been reidentified as X^3_Σ by U. Uhler, Dissertation, University of Stockholm, Sweden, 1954, and W. Weitzer, Jr. and D. McLeod, Jr., J. Phys. Chem. 69, 3468 (1965). The values of the three lowest electronic levels and quantum weights are obtained from Herzberg. A Δ state lying about 581 cm^{-1} above the ground state was reported by Phillips, loc. cit. A. V. Pettersson and B. Lindgren, Arkiv Fysik 22, 491 (1962); A. V. Pettersson, *ibid.*, 16, 185 (1959), reported two electronic states, $d^1\Sigma$ and $b^1\Pi$, at 1708.0 and 10814.4 cm^{-1} above $^1\Delta$ thus, the values of 2289 and 11395.4 are derived. The next two electronic levels, $^3\Sigma$ and $^3\Pi$, are obtained from Weitzer et al., and the value $1\bar{g} = 18502 \text{ cm}^{-1}$ is obtained from Rosen. The last three levels and the values of w_e , $w_e x_e$, B_e , a_e and r_e are taken from Herzberg, loc. cit. The moment of inertia is $5.226 \times 10^{-39} \text{ g cm}^2$.

The rather thorough studies of the emission spectra of TiO(g) have been summarized by R. W. B. Pearse and A. G. Gaydon, "The Identification of Molecular Spectra," 3rd Ed., John Wiley & Sons, Inc., New York, 1963, and A. Gatterer, J. Junkes, E. W. Salpeter, and B. Rosen, "Molecular Spectra of Metallic Oxides," Vatican Press, Vatican City, 1957.

TUNGSTEN MONOXIDE (W0)

(IDEAL GAS)

OPW = 199.8494

Ground State Configuration [5s²] g_{1/2}⁻
S_{298.15} = [58.7] gibbs/mol
ΔH_{f,0}^o = 101.7 ± 10 kcal/mol
ΔH_{f,298.15}^o = 101.6 ± 10 kcal/mol

Electronic Levels and Quantum Weights

E _i , cm ⁻¹	g _i
[0]	[3]
[14160]	[1]
[17211]	[2]
[19189]	[6]

σ = 1

r_e = [1.81] Å

Heat of Formation

The heat of formation, ΔH_{f,298}^o(W0,g) = 101.6 kcal/mol, was derived from the heat of reaction, ΔH_{r,298}^o = -42.0 kcal/mol for W0(g) → W(c) + O(g) with all JANAF auxiliary data. The value of ΔH_{r,298}^o was calculated by the third law method from the partial pressure data, which were determined mass-spectrometrically in the temperature range 2188° to 2475°K, by G. DeMaris, R. F. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. 32, 1373 (1960). The drift in the third law analysis was -20 ± 7 eu.

Heat Capacity and Entropy

The fundamental vibrational frequency, the ground state configuration, and the probable electronic levels for tungsten monoxide (g) were obtained from the infrared and ultraviolet spectroscopic investigations by matrix isolation by W. Weitzer, Jr., and D. McLeod, Jr., J. Mol. Spectry, 17, 276 (1965). The rotational constant B_e was calculated from an estimated bond distance, W-O = 1.81 Å. The value of x_e was calculated from the relation x_eu²/2 = 0.014 which was given by R. F. Barrow and A. D. Caunt, Proc. Roy. Soc. (London) 219A, 120 (1953). The constant, 0.014, was estimated, based on those for ZrO(g) and VO(g). The value of a_e was calculated from the Morse potential function.

(Ideal Gas) Mol. Wt. = 107.2194

MOL. WT. = 107.2194

ZIRCONIUM MONOXIDE (ZrO)

 $\omega_e x_e = 4 \text{ cm.}^{-1}$ $\omega_e = 978 \text{ cm.}^{-1}$ $B_e = 0.4142 \text{ cm.}^{-1}$ $r_e = 1.711 \text{ \AA}$ $\sigma = 1$

Heat of Formation.

The $\Delta H_f^{298.15} = 14.0 \pm 12 \text{ kcal. mole}^{-1}$ was calculated from the $\Delta H_f^{298.15} = 290.342 \pm 12.8 \text{ kcal. mole}^{-1}$ for the reaction $\text{Zr}(c) + \text{ZrO}_2(c) = 2\text{ZrO}(g)$. The value of $\Delta H_f^{298.15}$ was obtained by the third law analysis from the mass spectrometric studies of M. A. Chupka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. **28**, 1207 (1957). They observed the variation of the ZrO^+ ion intensity over the system $\text{Zr} + \text{ZrO}_2$ and reported equilibrium constants for the reaction $\text{Zr} + \text{ZrO}_2 \rightarrow 2\text{ZrO}$ in the range 2124-2322°K. The third law drift is $-58 \pm 28 \text{ e.u.}$

Heat Capacity and Entropy.

The ground state of $\text{ZrO}(g)$ was assumed to be $1\Sigma^+$ as determined from the matrix isolation spectra of W. Weltner, Jr., and D. McLeod, Jr., J. Phys. Chem. **69**, 3488 (1965). Previously this had been described as the lower state in the A band system reported by V. Uhler and L. Akerlind, Arkiv Fysik **10**, 431 (1955).

All molecular constants were obtained from Uhler and Akerlind, loc. cit., except $\omega_e = 978 \text{ cm.}^{-1}$ and $\omega_e x_e = 4 \text{ cm.}^{-1}$ which were calculated from ω and $\omega_e = 0.0023 \text{ cm.}^{-1}$ using the equations

$$\omega_e x_e = \frac{6 \sqrt{\omega_e x_e} \cdot B_e^3}{\omega_e} - \frac{6 B_e^2}{\omega_e} \quad \text{and} \quad \omega_e = \omega_e - 2 \omega_e x_e = 969.76 \text{ cm.}^{-1}$$

The higher electronic levels were obtained or estimated from the correlation diagram given by Weltner and McLeod, loc. cit.

OXYGEN, DIATOMIC (O₂) (REFERENCE STATE - IDEAL GAS)

Ground State Configuration 3Σ_g⁻ ΔH_f° 0 = 0

S_{298.15}° = 49.00 ± 0.01 cal. deg⁻¹ mole⁻¹ ΔH_f° 298.15 = 0

ω_e = 1580.245 cm.⁻¹ ω_ex_e = 12.071 cm.⁻¹ σ⁻ = 2

B_e = 1.445 cm.⁻¹ ω_e = 0.0158 cm.⁻¹ r_e = 1.2074 Å

Heat of Formation.

The heat of formation (ΔH_f°) for O₂(g) is zero at all temperatures, by definition.

Heat Capacity and Entropy.

The functions adopted here are based on those of H. W. Woolley, J. Research, Nat. Bur. Standards 40, 183 (1948), who used a direct summation to 5000°K. The spectroscopic constants used were the same as those listed by G. Herzberg, Spectra of Diatomic Molecules, D. Van Nostrand Co., 1950. Raman measurements of rotation-vibration levels by A. Weber and E. A. McInnis, J. Molec. Spect., 4, 195 (1960), support the constants selected by Herzberg which were changed on this table to apply to the naturally occurring isotopic composition given by D. Strominger, J. M. Hollander, and T. Seaborg, Rev. Mod. Phys. 30, 585 (1958).

The entropies listed by Woolley were reduced by 0.0065 cal. deg⁻¹ mole⁻¹ which was added by Woolley to account for the contribution due to the presence of both odd and even rotational levels in O₂¹⁶O¹⁷ and O₂¹⁶O¹⁸ molecules. This correction is not necessary when isotope mixing entropy is neglected, cf. W. F. Giauque and R. Overstreet, J. Am. Chem. Soc. 55, 1731 (1933).

$r_e = 1.30 \text{ \AA}$	

Heat of Formation.

The electron affinity of $O_2(g)$ has been measured in the electron detachment experiments of J. L. Pack and A. V. Phelps, J. Chem. Phys. **44**, 1870 (1966). The value reported is 0.43 ± 0.02 eV (9.92 ± 0.46 kcal/mol) which is in good agreement with the value 0.46 ± 0.1 eV selected by C. W. Beckett and E. C. Casady, Natl. Bur. Std. Report 6628, Jan. 1, 1965.

Heat Capacity and Entropy.

J. Rolfe, J. Chem. Phys. **40**, 1864 (1964), has deduced from fluorescence emission spectra of O_2^- in alkali halides, the vibrational constants and an excited electronic level. The $^2\Pi_g$ ground state is that predicted by molecular orbital theory and the first excited state should also be $^2\Pi_u$. By analogy with Cl_2^+ , which is isoelectronic, the first excited level is estimated to lie in the 20000 - 30000 cm^{-1} region. Thus, the level observed by Rolfe is assumed to be the first excited $^2\Pi_u$ state. The bond length is taken from F. R. Gilmore, The Rand Corporation, Memorandum RM-4034-1-Ph, AD 630997. B_e was calculated from the bond length and a_e was estimated from the above quantities using the Morse potential function relation.

The enthalpy at 0°K is -2.086 kcal/mol.

Angle O-P-O = 134° 4'

P-O distance = 1.485 Å

 $I_A = [10.81 \times 10^{-39}] \text{ g. cm.}^2$ $I_B = [9.933 \times 10^{-39}] \text{ g. cm.}^2$ $I_C = [0.677 \times 10^{-39}] \text{ g. cm.}^2$ $\sigma = 2$ Heat of Formation. $\Delta H_f^\circ 298.15$ was calculated from an estimated heat of dissociation ($270 \pm 25 \text{ kcal. mole}^{-1}$) reported by L. Brewer and G. M. Rosenblatt, Chem. Reviews, **61**, 257 (1961).

Heat Capacity and Entropy. The molecular constants selected for this table were estimated by J. S. Gordon. The molecular constants for PO₂(g) have been estimated by (1) J. S. Gordon, "Thermodynamic Data for Combustion Products," January 1960, Thiokol Chemical Corp., Reaction Motor Division, Danville, N. J.; (2) R. L. Fetter, V. N. DiStefano and S. N. Fox, "The Thermodynamic Functions of Some Combustion Products Containing Phosphorus-I," American Cyanamid Company; and (3) C. B. Henderson and R. S. Scheffer, "Survey of Thermochemical Data," January 1960, Atlantic Research Corp., Alexandria, Virginia. The entropies at 3000° calculated from these three estimates differ by less than 0.8 cal. deg.⁻¹ mole⁻¹.

Lead Dioxide (PbO₂) (crystal)

Mol. Wt. = 239.21

ΔH_f° 298.15 = -64.55 ± 0.16 kcal. mole⁻¹S° 298.15 = 18.3 ± 0.5 cal. deg.⁻¹ mole⁻¹

Heat of Formation. Recalculated from ΔH_f° 298.15 = 12.14 kcal. mole⁻¹ for the reaction: PbO(c) + 1/2O₂(g) = PbO₂(c) reported by M. Tschelitzow, Compt. rend., 100, 1458 (1885).

Heat Capacity and Entropy. C_p (69.9° to 297.2°K.) reported by R. W. Millar, J. Am. Chem. Soc. 51, 207 (1929). Above 298.15°K., the heat capacity value estimated by K. K. Kelley, U. S. Bur. Mines Bull. 594 (1960) was used. The two heat capacity curves were joined smoothly at 298.15°K. by graphical extrapolation.

Sulfur Dioxide (SO₂)

Bond Lengths and Angles S-O = 1.432 ± 0.003 Å. OSO = 119.53 ± 0.4°

Moments of Inertia I_A = 1.39046 × 10⁻³⁹ g. cm.² I_B = 8.13067 × 10⁻³⁹ g. cm.² I_C = 9.53376 × 10⁻³⁹ g. cm.² σ⁰ = 2

Heat of Formation

J. R. Eohman and P. D. Rossini, J. Research Nat. Bur. Standards **53**, 597 (1959), measured the heat of combustion of rhombic sulfur to SO₂. Changes due to different atomic weights and electrical constants though negligible have been made.

Heat Capacities and Entropies

The functions were calculated by J. Gordon, private communication, Feb. 2, 1961, using the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. **22**, 1442 (1954). Structural parameters are given by M. H. Sirvets, J. Chem. Phys. **19**, 938 (1951), obtained from microwave measurements. Frequencies were measured by R. D. Shelton, A. H. Nielsen, W. H. Fletcher, J. Chem. Phys. **23**, 2178 (1955) and **22**, 1791 (1954). A third law value of S°_{298.15} = 59.24 cal. deg.⁻¹ mole⁻¹ was obtained by W. F. Duanque and C. C. Stevenson, J. Am. Chem. Soc. **80**, 1389 (1958).

ΔH°₂₉₈ = -216.5 ± 0.4 kcal/mol
 ΔH°_{298.15} = -217.7 ± 0.4 kcal/mol
 ΔH°₁ = 847 ± 1.5°K (low quartz + high quartz)
 ΔH°₂ = 1079 ± 250°K (high quartz + high cristobalite)
 ΔH°_m = 1.84 ± 0.2 kcal/mol

Heat of Formation

The heat of formation is based on data of Wise (1) for combustion of SiO₂ (low quartz) and Si(c) in F₂ to form SiF₄(g). Good (2) burned a mixture of Si(c) and vinylidene fluoride polymer in oxygen in the presence of HF(aq) to form H₂SiF₆(aq HF). Combining this result with a previous heat of solution of quartz (3), the authors derived ΔH°₂₉₈ = -217.5 ± 0.5 kcal/mol. Agreement with the adopted value is excellent, considering the complexity of the latter scheme. Both schemes are independent of ΔH°_f (HF), although the polymer-Si scheme depends on the heat of dilution of HF(aq). Wise (1) has reviewed other data which confirm the adopted value rather than the oxygen combustion value (4) of -209.9 kcal/mol. Pertinent equilibrium data are analyzed on the table for SiO₂ (low cristobalite), while the calorimetric results are summarized below.

Source	Reaction	ΔH° ₂₉₈ , kcal/mol	ΔH° ₁ , kcal/mol
1. Wise (1963)	SiO ₂ (low quartz) + 2F ₂ (g) → SiF ₄ (g) + O ₂ (g)	-188.26 ± 0.78	-217.72 ± 0.34
2. Good (1964)	See text.	-	-217.5
3. Humphrey (1962)	Si(c) + 2O ₂ (g) → SiO ₂ (low quartz)	-209.9	-209.9

Heat Capacity and Entropy

Heat capacities below 300°K are based on data of Jones (5) and Westrum (6). Earlier data of Anderson (7) are in good agreement. The entropy is obtained from Cp° using S°₂ = 0.00001 eu. Cp° from 300° to 847°K is derived from adiabatic calorimetric data of Moser (8) and Sineil'nikov (9). The adopted Cp° is discontinuous at 847°K and ΔCp° = -2.17 gibbs/mol. Values above the transition temperature are based on data of Moser and on data up to 1473°K obtained with a thermal analysis method by Leonidov (10). Cp° is extrapolated linearly to higher temperatures.

From a review of data available before 1953, Kelley (11) selected almost identical enthalpies below 847°K but a value higher by 96 cal/mol at 900°K. The higher value, due to use of a larger ΔH°_f, was presumably based on Roth (12), Wietzel (13) and White (14) whose enthalpy data were given the most weight by Kelley. Near 900°K these three sets of data deviate from the adopted function by -150±30, +130±40 and +15±35 cal/mol, respectively; however, a recent enthalpy datum (15) obtained by transposed temperature drop calorimetry deviates by +75 cal/mol at 968°K.

Transition Data

T₁ is taken as 847 ± 1.5°K based on thermal analysis of many specimens by Kieth and Tuttle (16). Wide variations in T₁ for some specimens were attributed by the authors to small amounts of impurities. The discontinuity in the volume curve (17) during inversion from trigonal low quartz to hexagonal high quartz suggests that the transition should be treated as first order. Thus, the heat of transition is derived as (1011-854)/17 = 174 cal/mol, where 1011 ± 6 is (H°_{298.15} - H°_{847.15}) measured by Moser (8), 854 is the corresponding increment calculated from the JANAF Cp°, and 17 is an endpoint correction for the difference between the observed and adopted curves below 823.15°K. Some of the more recent data which confirm the adopted ΔH°₁ are summarized below.

Source	Method	ΔH° ₁ , kcal/mol
8. Moser (1936)	H and Cp from adiabatic calorimetry	0.174
9. Sineil'nikov (1953)	Integration of Cp from adiabatic calorimetry	0.143
10. Leonidov (1964)	Thermal analysis	0.198
17. Berger (1964)	ΔV with dT/dP = 0.076°K/atm	0.12
18. Berger (1965)	Microcalorimetric thermal analysis	0.156, 0.165, 0.178 ± 0.010
	Single crystal	0.124 to 0.193
	Various crushed samples	

Additional polymorphism of SiO₂ is discussed on the table for high cristobalite. Quartz has been superheated through the cristobalite region to some 300° above its metastable melting point. This melting point is calculated from the adopted tables as 1896 ± 50°K, which agrees well with the range 1673 - 1773°K indicated by the data of Mackenzie (18). The adopted tables predict the inversion of high quartz to high cristobalite at 1079 ± 250°K. Holmquist (20) tentatively placed this inversion at 1298 ± 25°K. ΔH°₂ and ΔH°_m are calculated from the differences in heats of formation of the appropriate phases at T₂ and T_m.

CRISTOBALITE, LOW (SiO₂)

(CRYSTAL)

GFW = 60.0848

O₂Si

ΔHf° = -215.9 ± 0.5 kcal/mol

ΔHf°_{298.15} = -217.1 ± 0.5 kcal/mol

ΔHt° = 0.321 ± 0.06 kcal/mol

S°_{298.15} = 10.372 ± 0.03 gibbs/mol

Tt = 543 ± 3°K (Low cristobalite + high cristobalite)

Heat of Formation

The heat of formation is calculated from that of quartz using ΔHr°₂₉₈ = 0.45 ± 0.15 kcal/mol for high quartz + high cristobalite, as determined by Holm(1) from ΔHsoln in an oxide melt. This value reduces to ΔHr°₂₉₈ = 0.60 kcal/mol for low quartz + low cristobalite. Kracek(2) obtained essentially the same value, ΔHr°₂₉₈ = 0.63 kcal/mol, from ΔHsoln in HF(aq, 74.7°C), while Hummel(3) found ΔHr°₂₉₈ = 1.80 kcal/mol from ΔHsoln in HF(aq, 26.5°C). The larger ΔHr° corresponds to a less negative ΔHf° (i.e., less stable) and suggests that the sample of Hummel has disorder approaching that of vitreous silica. Presumably, this disagreement arises from different methods of preparation of cristobalite from quartz. Holm heated for 24 hours at 1743°K, while Hummel heated for 4 hours at 1737°K. Hummel's sample was then ground and treated with dilute HF to remove amorphous surface layers created by grinding; particles smaller than 2.5 microns were used in order to obtain adequate rates of dissolution. Neither author gave X-ray or DTA evidence to confirm that the samples were the more stable, ordered form of cristobalite(13).

The calorimetric data are summarized below along with equilibrium data which confirm the adopted values of ΔHf° for cristobalite and quartz. Data from Matoba(5) and Rein(6) were reduced to the standard state of Si(l) using activity coefficients from the curves of (10).

Source	Method	Reaction	Range, T, °K	No. of Points	ΔHr° ₂₉₈ , kcal/mol	Drift, au	ΔHf° ₂₉₈ , kcal/mol

*Values at T are from second law analysis while those at 298.15°K are from third law.

A. SiO₂ (quartz, low or high) = SiO₂ (cristobalite, low or high)

B. SiO₂ (high cristobalite) + 2H₂(g) = Si(l) + 2H₂O(g)

C. SiO₂ (high cristobalite) + 2C(graph) = Si(l) + 2CO(g)

D. SiO₂ (high cristobalite) + 2SiC(β) = 3Si(l) + 2CO(g)

E. SiO₂ (high cristobalite) + 3C(graph) = SiC(β) + 2CO(g)

Heat Capacity and Entropy

Cp° below 300°K is based on data of Westrum(11). Earlier data of Anderson(12) are in satisfactory agreement. The entropy is obtained from Cp° using S° = 0.0007 eu. Cp° above 300°K is derived from enthalpy data of Moesman(13) and White(14). The former deviate from the adopted functions by -0.7 to 0.51 and the latter by +0.44. Although the functions above 300°K appear to be reliable, it would be desirable to have new data for a well-characterized sample (see Transition Data).

Transition Data

Low cristobalite is metastable with respect to quartz but persists up to Tt. Tt is taken as the temperature at the peak in the heating curve for well-ordered cristobalite; however, see (15, 16) for detailed discussions of temperatures about 25° lower which were found from cooling curves. ΔHt° is derived from enthalpy data(13, 14) for high cristobalite using the adopted enthalpy for the low form. The enthalpy data of Moesman(13) gave a lower Tt which suggests that the sample was less well-ordered than desirable. ΔHt° is confirmed, however, by other data which are summarized below. Additional polymorphism is discussed on the table for high cristobalite.

Source	Method	ΔHt°, kcal/mol
13. Moesman (1941)	Enthalpy data	0.321
17. Berger (1965)	Microcalorimetric thermal analysis	0.318±0.018
18. Majumdar (1964)	ΔV and dT/DP	0.27

CRISTOBALITE, HIGH (SiO₂)

(CRYSTAL)

GFW = 60.0848

$\Delta H_f^{298.15} = -216.417$ kcal/mol
 $\Delta H_f^{\circ} = 0.321 \pm 0.06$ kcal/mol
 $\Delta H_f^{\circ} = 0.48 \pm 0.15$ kcal/mol
 $\Delta H_m^{\circ} = 2.29 \pm 0.5$ kcal/mol

Heat of Formation

The heat of formation is calculated from that of low cristobalite by addition of $\Delta H_f^{\circ} = 0.321$ kcal/mol and the difference between $H_{SiO_2}^{\circ} - H_{SiO_2}^{\circ}$ for low and high forms.

Heat Capacity and Entropy

C_p° is derived from enthalpies of Nosenman (1) and White (2), whose data deviate from the adopted functions by -0.6 to +0.5% and +0.9 to 0.0%, respectively. White's deviations for cristobalite have a magnitude and trend similar to his deviations for quartz and vitreous silica. Data of Wietzel (3) for his sample prepared at 1600°C deviate by +3% at 673°K and +1.6% at 1973°K. C_p° below 543°K is smoothly extrapolated to give the proper trend in the Gibbs energy, but the heat capacity at 298°K is not realistic. The entropy is calculated in a manner analogous to that of the heat of formation.

Transition Data

Literature on the polymorphism of SiO₂ is voluminous but is summarized in detail in recent books by Sosman (4) and Eitel (5). The known phases of SiO₂ include quartz, tridymite(?), cristobalite, vitreous silica and the more recently discovered high pressure phases. Muan (6) concisely reviewed the still controversial question of whether tridymite is stabilized only by the presence of foreign ions or whether it is a stable phase of SiO₂ intermediate between quartz and cristobalite. Transitions among the different phases are generally sluggish because of large energy barriers to the structural change and small differences in Gibbs free energies. As a result, the phases often persist far into metastable regions. In contrast, transitions within a particular phase are rapid and reversible (i.e., the low + high inversions of quartz or cristobalite).

High cristobalite is the stable phase near T_m . It becomes metastable with respect to quartz at lower temperatures but persists down to the high + low inversion at 543°K (see table for low cristobalite). The high form is cubic and the low form tetragonal (12, 13).

The adopted tables give 1079+250°K as the temperatures at which $\Delta G^{\circ} = 0$ for high quartz + high cristobalite; which, in turn, is taken from $\Delta H_f^{298} = 0.45 \pm 0.15$ kcal/mol obtained by Holm (7) from ΔH_{soln} measurements in an oxide melt. It is apparent that T_t is extremely sensitive to small changes in G or H . Holmquist (8) tentatively placed this inversion at 1298+25°K but did observe cristobalite formation at temperatures as low as 1171°K.

Melting Data

Melting point data were reviewed by Schneider (9) and adjusted to the 1948 International Temperature Scale. The adopted melting point for cristobalite is based on Greig (10). ΔH_m° is calculated as the difference in ΔH_f° for liquid and crystal at T_m . Mackenzie et al. (11) showed that cristobalite may be superheated by as much as 40° above T_m due to its slow rate of fusion.

(LIQUID)

GFW = 60.0848

$$\Delta H_{298.15}^{\circ} = 11.455 \pm 0.3 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = -215.74 \text{ kcal/mol}$$

$$T_m = 1996 \pm 5^{\circ}\text{K (high cristobalite} \rightarrow \text{liquid)}$$

$$\Delta H_m^{\circ} = 2.29 \pm 0.5 \text{ kcal/mol}$$

Heat of Formation

The heat of formation is calculated from that of quartz using $\Delta H_{970}^{\circ} = 1.45 \pm 0.15 \text{ kcal/mol}$ for high quartz $\rightarrow \text{SiO}_2(l)$, as determined by Holm (1) from ΔH_{soln} in an oxide melt. This value reduces to $\Delta H_{298}^{\circ} = 1.96 \text{ kcal/mol}$ for low quartz $\rightarrow \text{SiO}_2(l)$ and is consistent within $\pm 0.3 \text{ kcal/mol}$ with other calorimetric data summarized below. Earlier results were reviewed by Hummel (4).

Heat Capacity and Entropy

C_p° below 300°K is based on data of Flubacher (5) and Westrum (6) for samples annealed at 1100 and 1070°C, respectively. Data of Turdakin (7) are higher by about 1 percent in the range 60-160°K and at 300°K but are in agreement elsewhere. The entropy is calculated from C_p° using $S_{2.34}^{\circ} - S_0^{\circ} = 0.0001 \text{ eu}$ and $S_0^{\circ} = 1.098 \text{ eu}$. C_p° data (8) for a different sample annealed at 1300°C yield an entropy larger by $<0.04 \text{ eu}$. Earlier data were reviewed by Kelley (9). The residual entropy is calculated from $S_0^{\circ} = S_{996}^{\circ} - (S_{996}^{\circ} - S_0^{\circ}) = 41.258 - 40.160 = 1.098 \text{ eu}$, where 40.160 is obtained from the adopted functions, while 41.258 is the sum of $\Delta S_m^{\circ} = 1.447 \text{ eu}$ and $S_0^{\circ} = 40.111 \text{ eu}$ for high cristobalite. We estimate the uncertainty as $\pm 0.3 \text{ eu}$, primarily from the uncertainty in ΔH_m° .

C_p° above 300°K is based on adiabatic calorimetric data of Moser (5) up to 900°K. Enthalpy data of White (10) and Fischer (11) are in excellent agreement. C_p° from 900 to 1500°K is derived from enthalpy data of Southard (12) and White (10). Maximum deviation of the data from the adopted values in this range is 0.5 percent. Enthalpy data of Egan (13) and Kelley (14) deviate from the adopted values by less than 1 percent in the range 1000-1500°K, although large positive deviations appear at lower temperatures.

In the region 1500-1700°K, the adopted C_p° shows a rapid, sigmoidal rise which is suggested by the enthalpy data of Wiestel (15). This is presumed to be the glass transition region in which C_p° rises to that of the stable liquid. C_p° above 1700°K is estimated as 20.5 gibbs/mol or 6.83 gibbs/g-atom. This value is consistent with the enthalpy data (15) and with liquid heat capacities of Al_2O_3 , $\text{Na}_2\text{Si}_2\text{O}_5$ and Na_2SiO_3 .

Melting Data

The melting point of high cristobalite is $1996 \pm 5^{\circ}\text{K}$, while the metastable melting point of high quartz is $1696 \pm 50^{\circ}\text{K}$. ΔH_m° is the difference between ΔH° for liquid and high cristobalite at T_m . Values ranging from 1.8 to 3.6 kcal/mol have been derived from various interpretations of phase diagrams (1).

Rotational Constant: B₀ = [0.2193] cm⁻¹

Heat of Formation

The adopted value is based on the data summarized below. Margrave (1) has reported a value of $\Delta H_f^\circ_{298} = 140.9 \pm 1$ kcal/mol but details are not yet available. Assuming that this corresponds to reaction A below, we calculate $\Delta H_f^\circ_{298} = -75.5$ kcal/mol. Firsova (2) reported two values of the sublimation pressure which were derived from Knudsen effusion data using auxiliary data for SiO(g). Porter (3) derived two pressures from a mass spectrometric study and also obtained a 2nd Law value for ΔH_f° from ion intensities. The resulting range for $\Delta H_f^\circ_{298}$, 136 to 141 kcal/mol, is consistent with the lower limit of 130 kcal/mol obtained by Bergman (3) from a method involving explosion in a spherical bomb. An alternative analysis of the mass spectrometric data (4) using the gas phase reaction B suggests an even higher ΔH_f° of 148 kcal/mol. The adopted ΔH_f° corresponds to $\Delta H_f^\circ_{298} = 143.4 \pm 4$ kcal/mol and to $\Delta H_{\text{atom}}^\circ = 297.3 \pm 8$ kcal/mol.

Source	Reaction	Method	Range, °K	$\Delta H_f^\circ_{298}$, kcal/mol	Drift
Margrave (1967)	A	-	-	140.9 ± 1	-

	A	Ion intensities	1750-1980	136 ± 8	-76.8
	B	Knudsen mass spec.	1800-1900	-2	-80
	A. SiO ₂ (high cristobalite) = SiO ₂ (g)	-	-	-44.8 ± 1.2	-23
	B. SiO(g) + 1/2 O ₂ (g) = SiO ₂ (g)	-	-	-68.8	-

Heat Capacity and Entropy

Point group, ground state quantum weight and the linear symmetrical configuration are estimated by analogy with the properties of CO₂. From the bond lengths in SiO, CO₂ and CO, the length in SiO₂ is estimated as 1.509 × 1.180/1.128. Bond lengths and atomization energies for these molecules are reasonably consistent with the existence of six-electron bonds in the monoxides and four-electron bonds in the dioxides (5). Vibrational frequencies are estimated from a valence bond calculation using force constants, $k = 9 \times 10^5$ and $k_6/k_2 = 0.3 \times 10^5$ dyne/cm, which are obtained from those of SiO, CO₂ and CO. The moment of inertia is 12.76 × 10⁻³⁹ g cm².

TITANIUM DIOXIDE, ANATASE (TiO₂)

(CRYSTAL)

QFW = 79.8988

O₂Ti

$\Delta H_f^\circ = -221.8 \pm 1 \text{ kcal/mol}$
 $\Delta H_{298}^\circ = -223.0 \pm 1 \text{ kcal/mol}$
 $\Delta H^\circ = [0.0] \text{ kcal/mol}$
 $\Delta H_m^\circ = \text{Unknown}$
 $\Delta H_{298}^\circ = 161 \text{ kcal/mol}$

$S_{298}^\circ = 11.93 \text{ gibbs/mol}$
 $T_f = 918^\circ \text{K}$
 $T_m = \text{Unknown}$

Heat of Formation.

The value of ΔH_f° (anatase) is obtained from J. L. Margrave and B. D. Kybett, "Thermodynamic and Kinetic Studies of Borides and Other Refractory Materials at High Temperatures," Tech. Rept. AFML-TR-65-123, August 1965, Rice University, Houston, Texas. The authors measured the heat of fluorination of anatase, according to the reaction $\text{TiO}_2 (\text{anatase}) + 2\text{P}_2(\text{g}) = \text{TiF}_4(\text{c}) + \text{O}_2(\text{g})$, but no experimental data were given.

F. W. Vahldiek, J. Less-Common Metals 11, 99 (1966), studied the irreversible anatase-rutile phase transition at pressures of 3.8 to 24 kbars and temperatures 20 to 1000°C. Isothermal phase-transition studies were also carried out at 1 bar pressure and 880-950°C. From the slope, dT/dP , the enthalpy differences between rutile and anatase were calculated to be -2.79 and -2.89 kcal/mol at 1183 and 1223°K, respectively. Using these data and $\Delta H_f^\circ(\text{rutile}) = -255.8 \text{ kcal/mol}$, the value of $\Delta H_f^\circ(\text{anatase})$ is derived as -223.23 kcal/mol, which is in excellent agreement with the adopted value.

Heat Capacity and Entropy.

Low temperature heat capacities, 52-296°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 59, 218 (1947).

Enthalpy data were determined in the range 416-1305°K by B. F. Naylor, J. Am. Chem. Soc. 58, 1077 (1946), and in the range 580 - 1000°K by J. Lietz, Hamburger Beitr. Angew. Mineral. Kristallphysik 1, 229 (1956). High temperature heat capacities are derived from the enthalpy data, subject to the constraint that there be a smooth joint at 298°K. The resulting enthalpies are higher by 1 to 3% than those measured by Lietz and lower by 1 to 4% than those measured by Naylor. Values above 1300°K are smoothly extrapolated. S_{298}° is calculated from the low temperature C_p° using $S_{50}^\circ = 0.45 \text{ eu}$.

In view of the discrepancies in the enthalpy data, a review of the anatase samples is pertinent. Those of Shomate and Lietz were prepared by precipitation of the hydrated oxide and conversion to the oxide at 550 - 565°C. Shomate's starting material was high purity Ti and the product analyzed as 99.3% TiO₂. Lietz' starting material was high purity TiCl₄. Naylor's sample, obtained from J. T. Baker Co., was dried at 1050°C; spectrographic analysis indicated 0.3% SiO₂ and 0.15% CaO. All three samples gave only the X-ray lines of anatase.

Transition Data.

$T_m = 918^\circ \text{K}$ and $\Delta H^\circ = 0.040 \text{ kcal/mol}$ have been reported by J. Lietz, loc. cit. A. Schröder, Z. Kryst. 65, 493 (1928), suggested a transition temperature at 915°K on the basis of a peak in the thermal expansion curve. Lietz reported $\Delta H^\circ = 0.04 \text{ kcal/mol}$, but this value is not adopted since its magnitude is much less than the uncertainty in the selected enthalpies. Further study is desirable to confirm this transition.

Heat of Sublimation.

ΔH_{298}° is calculated as the difference between ΔH_f° for TiO₂(g) and TiO₂(anatase).

Dec. 31, 1960; Mar. 31, 1967

TITANIUM DIOXIDE, RUTILE (TiO₂)

OPW = 79.8988

(CRYSTAL)

$\Delta H_f^\circ = -224.6 \pm 1 \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = -225.8 \pm 1 \text{ kcal/mol}$
 $\Delta H_m^\circ = [16] \text{ kcal/mol}$
 $\Delta H_{298.15}^\circ = 163.8 \text{ kcal/mol}$

$S_{298.15}^\circ = 12.03 \text{ gibbs/mol}$

$T_m = 2143^\circ\text{K}$

Heat of Formation.

The heat of formation for rutile has been determined from combustion calorimetry by many investigators. Several of the more consistent ΔH_f° values are listed in the table below. Ariya et al.³ reported that the composition of the rutile obtained from combustion of Ti(c) was between TiO_{1.94} and TiO_{1.95}. Emf studies by R. N. Blumenthal and D. H. Whitmore, J. Electrochem. Soc. 110, 92 (1963), indicate that at 1200°K there is a two-phase region beginning at about TiO_{1.98}. If this region extends to 298°K, then the non-atmospheric combustion products probably involve a mixture of two phases. Meh et al.⁴ applied an approximate energy correction for incomplete combustion which corresponds to 0.7 - 1.5 kcal/mol in ΔH_f° . Analogous corrections were applied by Ariya et al.³ but were not mentioned by Neumann et al.^{1,2} and Humphrey.⁵

The ΔH_f° value reported by Margrave and Kybett⁵ was obtained by fluorine bomb calorimetry, according to the reaction $\text{TiO}_2(\text{rutile}) + 2\text{F}_2(\text{g}) = \text{TiF}_4(\text{c}) + \text{O}_2(\text{g})$. No experimental data were given.

Comparison of the fluorine result with the oxygen results indicates that the magnitude of the corrections for the oxygen data is reasonable, probably within $\pm 1 \text{ kcal/mol}$, provided that the fluorine data refer to stoichiometric TiO₂. Corresponding ΔG_f° corrections for TiO_{2-x} are of the same order of magnitude when estimated from the partial molar free energy values given by P. Korstad, J. Phys. Chem. Solids 23, 1579 (1962), and J. B. Moser, R. N. Blumenthal and D. H. Whitmore, J. Am. Ceram. Soc. 49, 384 (1965).

The ΔH_f° value determined by Meh et al.⁴ is adopted.

Heat Capacity and Entropy.

The low temperature heat capacities, 10 - 297.7°K, have been measured by the following investigators: P. H. Keesom and N. Pearlman, Phys. Rev. 112, 800 (1936), 10 - 20°K; J. S. Dugdale, J. A. Morrison and D. Patterson, Proc. Roy. Soc. (London) A224, 228 (1954), 20 - 50°K; H. Shomate, J. Am. Chem. Soc. 69, 218 (1947), 52.5 - 297.7°K; and H. J. McDonald and H. Seltz, J. Am. Chem. Soc. 61, 2405 (1939), 68.78 - 295.0°K. The first three sets of Cp data are joined smoothly and extrapolated to 298°K, yielding $S_{298}^\circ = 12.03 \text{ eu}$, based on $S_{10}^\circ = 0.0014 \text{ eu}$. The Cp values reported by McDonald and Seltz seem too high and are not used.

The high temperature enthalpies have been determined by B. P. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), 393.5 - 1746°K; J. S. Arthur, J. Appl. Phys. 21, 732 (1950), 293.2 - 1073.2°K; and J. Lietz, Hamburger Beiträge Angew. Mineral u. Kristall Phys. 1, 229 (1956), 577.7 - 1293.0°K. The Cp values are derived from the data of Lietz and join smoothly at 298°K with the low temperature data. Deviations from the selected values are -1.6 to +1.0% for Lietz, -5.1 to +4.0% for Arthur, and +6.6 to -0.8% for Naylor. The data point of Lietz at 947.95°K is omitted as a probable typographical error. The largest deviations in the case of Naylor and Arthur are near 400 and 500°K, respectively.

The mean specific enthalpies have also been measured by L. P. Nilsen and O. Pettersson, Z. Physik, Chem. 1, 27 (1987), 373.2 - 717.2°K.

The samples used by Keesom and Pearlman, Dugdale et al., Shomate, Arthur and Lietz were of high purity, according to chemical and spectroscopic analysis. However, the sample employed by Naylor was black-colored and chemical analysis gave 97.9% TiO₂. The main impurities were: 0.55% ZrO₂, 0.50% SiO₂, 0.27% V₂O₅, 0.15% CaO, 0.15% Fe₂O₃ and 0.1% Al₂O₃. The sample of McDonald and Seltz was obtained commercially. Therefore the results reported by Naylor and McDonald et al. are given the least weight.

Melting Data.

See TiO₂(1) table for details.

Heat of Sublimation.

The difference between ΔH_{298}° for TiO₂(g) and TiO₂(rutile) is ΔH_{298}° .

TITANIUM DIOXIDE (TiO₂)

(LIQUID)

GFW = 79.8988

S_{298.15} = [18.934] gibbs/mol
ΔH_{298.15} = [-210.726] kcal/mol
ΔHm° = [16] kcal/mol

Tm = 2143°K

Heat of Formation.

The ΔH_f²⁹⁸(l) is calculated from ΔH_f²⁹⁸(rutile, c) by adding ΔHm° and the difference between S₂₁₄₃° - S_{298.15}° for TiO₂(rutile, c) and TiO₂(l).

Heat Capacity and Entropy.

The heat capacity of TiO₂(l) is estimated on the basis of 7.0 gibbs/g-atom. The value of S₂₉₈° is obtained in a manner analogous to that of the heat of formation.

Melting Data.

The melting point of TiO₂(rutile) has been measured by many investigators. Eleven pertinent Tm values were reviewed and corrected, according to the International Temperature Scale of 1948, by S. J. Schneider, Natl. Bur. Std. Monograph 68, October 10, 1963. The adopted melting point is obtained from G. Brauer and W. Litke, J. Inorg. Nucl. Chem. 16, 67 (1960). These authors found that TiO₂ loses oxygen on heating and the solid residue consists of a non-stoichiometric compound of the composition TiO_{2-x}. The value of the coefficient x depends on the temperature and on the oxygen pressure of the gaseous phase. Under oxygen pressures greater than or equal to 300 torr, the solid residue was TiO_{2.000} within the sensitivity of chemical analysis; however, color of the residue was a more sensitive indicator of composition. At pressures of 600 torr or greater, the residue was bright yellow rather than blue-gray and the melting point was constant at the maximum value of 2143 ± 15°K. This value is adopted.

The heat of melting is calculated using an estimated entropy of melting, ΔSm° = 2.5 eu/g-atom.

Heat of Formation.

P. W. Gilles, K. D. Carlson, H. F. Frenzen, and P. G. Wahlbeck, *J. Chem. Phys.* **45**, 2461 (1967), studied the vaporization behavior of the titanium-oxygen system and found that Ti₃O₅ is the final residue of both higher and lower titanium oxides; hence Ti₃O₅ is the congruently vaporizing phase. This conclusion was obtained by measurement of the change in composition of the solid residue accompanying vaporization as determined by x-ray diffraction, chemical analysis, and color of sample.

From mass spectrometric studies over Ti₃O₅(s) near 2000°K, P. G. Wahlbeck and P. W. Gilles, *J. Chem. Phys.* **45**, 2465 (1967), concluded that the partial pressure of TiO₂ is probably less than 1% of the pressure of TiO produced by the main vaporization, Ti₃O₅(s) = 3 TiO(g) + 2 O(g). This yields ΔH⁰₂₀₀₀ ≥ 228 kcal for the reaction Ti₃O₅(s) = 2 TiO₂(g) + TiO(g) and ΔH⁰₂₉₈ TiO₂(g) ≥ -62 kcal/mol, which is the value adopted. The corresponding atomization energy is D₀⁰ ≤ 292 kcal/mol.

Earlier vaporization studies over TiO₂-x gave apparent heats of formation which are more negative by 20-35 kcal; however, the results appear to be uncertain due to lack of sufficient auxiliary data for the oxygen-deficient condensed phase. Knudsen effusion-mass spectrometric studies of J. Berkowitz, W. A. Chupka and M. G. Inghram, *J. Phys. Chem.* **61**, 1559 (1957), revealed the initial evolution of large amounts of MoO₃(g), suggesting that the reduction of TiO₂ is enhanced by the Mo cell. In order to reduce the effect of the initial high rate of evaporation, W. O. Groves, M. Hoch and H. L. Johnston, *J. Phys. Chem.* **59**, 127 (1955), conducted their Knudsen effusion-weight loss studies on TiO₂. Preferential loss of oxygen during the experiment, as indicated by a residue of TiO_{1.85}, was apparently ignored. Groves et al. estimated the activity of TiO₂(rutile) as 0.53; Berkowitz et al. assumed unit activity but did not indicate the composition of their condensed phase. These activities may be in serious error due to the presence of a series of distinct phases between TiO_{1.8} and TiO_{1.9} [cf. S. Andersson, *Acta Chem. Scand.* **14**, 1161 (1960)] and to the possible existence of a two phase region near TiO_{1.99} [cf. R. N. Blumenthal and D. H. Whitmore, *J. Electrochem. Soc.* **110**, 92 (1963)]. Second and third law analyses of the data, using the authors' original assumptions, are summarized below. No weight is given to these results.

Investigator	Temperature, °K	No. of Points	ΔH ⁰ ₂₉₈ kcal/mol	Drift, eu
Groves et al.	1849 - 2010	14	128.7 ± 7.5	130.1
Berkowitz et al.	1891	3	142.7 ± 5**	142.8

*Calculation based on the third law ΔH⁰₂₉₈.

**Obtained from the temperature variation experiments, reported in the original paper.

Heat Capacity and Entropy.

The molecular structure is assumed to be linear. The Ti-O bond distance is estimated as the same as that in TiO(g). The vibrational frequency 940 cm⁻¹ was observed in matrix isolation by W. Waltner, Jr., and D. McLeod, Jr., *J. Phys. Chem.* **69**, 3488 (1965). The other two frequencies are calculated, based on the valence bond method as suggested by Berkowitz, Chupka and Inghram, loc. cit. The moment of inertia is 1.3944 x 10⁻³⁶ g cm².

Heat Capacity and Entropy.

E. G. King, W. W. Weiler, and A. U. Christensen, U. S. Bur. Mines RI 5664, (1960), have measured the low temperature heat capacities from 53° to 297°K and high temperature enthalpy changes from 398° to 1800°K by drop calorimetry. The low temperature and high temperature heat capacities were joined smoothly at 298.15°K. The entropy was obtained from the heat capacities based on S°₂₉₈ = 0.52 eu. It is possible that at temperatures below 50°K the entropy due to the uncoupling of the d² electrons will appear, contributing an additional 2.2 eu.

Temperature of Decomposition.

Tungsten dioxide (c) has no melting point, since disproportionation occurs to yield W(c) and WO₃(l) before melting starts. The Td is calculated as the temperature at which ΔG equals zero for 3 WO₂(c) = 2 WO₃(l) + W(c).

Heat of Sublimation.

June 30, 1962; Sept. 30, 1963

The heat of sublimation was calculated from the difference between the heats of formation of WO₂(g) and WO₂(c).

O₂W

TUNGSTEN DIOXIDE (WO₂)

(CRYSTAL) GFW = 215.8488

S°₂₉₈.15 = 12.08 ± 0.07 gibbs/mol
 Td = 1997°K
 ΔH°_f = -139.75 ± 0.21 kcal/mol
 ΔH°_f_{298.15} = -140.94 ± 0.21 kcal/mol
 ΔH°_f_{298.15} = 159.24 kcal/mol

Heat of Formation.

The adopted heat of formation, -140.94 ± 0.21 kcal/mol, was determined by combustion calorimetry by A. D. Mah, *J. Am. Chem. Soc.* 81, 1582 (1959). R. C. Griffiths, *J. Electrochem. Soc.* 105, 398 (1958), has measured the heat of combustion to WO₃(c) which yields ΔH°_f₂₉₈ (WO₂, c) = -139.8 ± 1.5 kcal/mol when recalculated with ΔH°_f₂₉₈ (WO₃, c) = -201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products.

Recent equilibrium data yield essentially the same average of the heat of formation by the third law method. The results are presented as follows.

Author	Reaction*	Temp. (°K)	No. of Points	ΔH° _f ₂₉₈ (kcal/mol)	Drift (eu)	ΔH° _f ₂₉₈ (kcal/mol)

Heat of Formation.

G. DeMaris, R. P. Burns, J. Drowart and M. G. Inghram, J. Chem. Phys. **32**, 1373 (1960), have reported the partial pressures of WO₂(g), WO₃(g) and O(g) in a mass spectrometric study of aluminum oxide vaporized from a tungsten cell from 2185° to 2475°K. The adopted value, ΔH°_f°₂₉₈ (WO₂g) = 18.3 ± 7 kcal/mol, was calculated from ΔH°_f°₂₉₈ = -100.9 kcal/mol for W(c) + 2 O(g) → WO₂(g), which was obtained from third law treatment of their partial pressure data, using all JANAF functions. The third law drift is 15.0 ± 5.2 eu. Partial pressures of WO₂(g), WO₃(g) and O(g) at 2242°K have also been reported by W. A. Chupka, J. Berkowitz and C. F. Glease, J. Chem. Phys. **30**, 827 (1959), in a mass spectrometric study of beryllium oxide in a tungsten cell. Similar calculation gives ΔH°_f°₂₉₈ = -105.9 kcal/mol, which yields ΔH°_f°₂₉₈ (WO₂g) = 13.2 kcal/mol.

Heat Capacity and Entropy.

The WO₂(g) was assumed to have a C_{2v} symmetry with a bond angle O-W-O = 110°. The bond distance W-O was estimated to be the same as that in WO(g). The symmetric and asymmetric stretching frequencies were obtained from the infrared spectrum of WO₂ in a neon matrix by W. Weitzer, Jr., and D. McLeod, Jr., J. Mol. Spectry. **11**, 276 (1965). The bending vibrational frequency (300 cm⁻¹) was estimated by comparison with other dioxides. The electronic levels and quantum weights were estimated from W⁴⁺ ion by analogy with Mo⁴⁺ ion. The three principal moments of inertia are: I_A = 4.8776 x 10⁻³⁹, I_B = 1.1680 x 10⁻³⁸ and I_C = 1.6558 x 10⁻³⁸ g cm².

O₂W

Zirconium Dioxide (ZrO₂)

(Crystal) Mol. Wt. = 123.2188

O₂ZrZIRCONIUM DIOXIDE (ZrO₂) (CRYSTAL) MOL. WT. = 123.2188

$$\Delta H_f^0 = -261.0 \pm 0.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 298.15 = -262.3 \pm 0.4 \text{ kcal. mole}^{-1}$$

$$\Delta H_c^0 = 1.42 \pm 0.1 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^0 = [20.8] \text{ kcal. mole}^{-1}$$

$$S^0 298.15 = [12.035 \pm 0.08] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_f = 1478 \pm 5^\circ \text{K.}$$

$$T_m = 2950^\circ \text{K.}$$

Heat of Formation.

The $\Delta H_f^0 298.15 = -263.1 \pm 0.5 \text{ kcal. mole}^{-1}$ measured (by combustion calorimetry) by O. L. Humphrey, J. Am. Chem. Soc. 75, 978 (1954) and E. J. Huber, Jr., E. L. Head and C. E. Holley, Jr., J. Phys. Chem. 58, 3040 (1954) respectively. Also the heat of formation was measured calorimetrically by B. Neumann, C. Kröger and H. Kunz, Z. anorg. Chem. 218, 579 (1934), by W. A. Roth, E. Böger, and H. Siemensen, ibid., 239, 321 (1938) and by A. Sievert, A. Gotta and S. Halberstadt, ibid., 187, 185 (1930) and was found -258.2, -258.8 and -256.1 kcal. mole⁻¹ respectively. However more weight was given to the Humphrey and Huber values.

Heat Capacity and Entropy.

The low temperature heat capacities, 54.3-295°K., were measured by K. K. Kelley, Ind. Eng. Chem. 35, 377 (1944). The heat capacities in the temperature range 298-1478°K. were calculated by using the J. P. Coughlin and E. O. King equation $C_p = 16.64 + 1.80 \times 10^{-5} T - 3.36 \times 10^{-8} T^2$ obtained from their measured enthalpy data in the range 398.8 - 1841°K., J. Am. Chem. Soc. 72, 2282 (1950). The values from the two sources join smoothly at 298°K. Above the transition 1478°K. the heat capacity was taken as constant at 17.80 cal. mole⁻¹ deg.⁻¹, Coughlin and King, loc. cit. The entropy was calculated at 54.30 using the Debye and Einstein function $D(\frac{345}{T}) + E(\frac{513}{T})$ given by Kelley, loc. cit. The value of $S_{54.3}^0 = 0.5507 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

T_f and ΔH_f^0 were taken from Coughlin and King loc. cit.

Melting Data.

The T_m and ΔH_m^0 were taken from Natl. Bur. Standards Circ. 500 Washington (1952).

O₂Zr

Zirconium Dioxide (ZrO₂)

(Liquid)

Mol. Wt. = 123.2188

O₂Zr

MOL. WT. = 123.2188

(LIQUID)

ZIRCONIUM DIOXIDE (ZrO₂)

$$\Delta H_f^{298.15} = [244.55] \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{298.15} = [20.8] \text{ kcal. mole}^{-1}$$

$$\Delta H_v^{298.15} = [149.2] \text{ kcal. mole}^{-1}$$

$$S^{298.15} = [17.04] \text{ cal. deg.}^{-1}$$

$$T_m = 2950^\circ \text{K.}$$

$$T_b = 4540^\circ \text{K.}$$

Heat of Formation:

The $\Delta H_f^{298.15} (l)$ was obtained from $\Delta H_f^{298.15} (c)$ by adding $\Delta H_m^{298.15}$ and the difference between $T_m^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

A glass transition was assumed at 2000°K. The heat capacity below 2000°K. was obtained from the heat capacity of the crystal. Above 2000°K. the heat capacity was assumed constant and estimated to be 21.0 cal. deg.⁻¹ mole⁻¹ or 7 cal. deg.⁻¹ per g-atom as suggested by O. Kubaschewski and E. L. Evans, "Metallurgical Thermochemistry" Pergamon Press, New York (1958). The entropy was obtained in a manner analogous to that of the heat of formation.

Melting Data.

See ZrO₂(c) table.

Vaporization Data.

T_b was calculated as the temperature at which the free energy change of the reaction $\text{ZrO}_2(l) \rightarrow \text{ZrO}_2(g)$ approaches zero. The difference between $\Delta H_f^{298.15}$ for $\text{ZrO}_2(g)$ and $\text{ZrO}_2(l)$ is $\Delta H_v^{298.15}$.

Heat of Formation.

The ΔH_f° 298.15 = -68.4 ± 11 kcal. mole⁻¹ was calculated from the ΔH_f° 298.15 = 193.867 ± 11.25 kcal. mole⁻¹ for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$. The value of ΔH_f° 298.15 was obtained by the third law method using the determined vapor pressures (at the range 2331-2480°K) by W. A. Chapka, J. Berkowitz and M. G. Inghram, J. Chem. Phys. 25, 1207 (1957). They observed the variation of the ZrO_2^+ ion intensity over ZrO_2 and reported equilibrium constants for the reaction $ZrO_2(c) \rightarrow ZrO_2(g)$ in the range 2331-2480°K. The third law drift is 80 ± 25 e.u.

Heat Capacity and Entropy.

The vibrational frequencies $\nu_1 = 884$, $\nu_2 = 1371$, $\nu_3 = 818$ and angle $O-Zr-O = 109^\circ$ were obtained from M. J. Linevsky, Spectroscopic Studies of the Vaporization of Refractory Materials, Technical Report Nr. AFML TR-64-420 Air Force Materials Lab. Research and Technology Division, Wright Patterson Air Force Base, Ohio (1965). The bond distances (r_e) $O-Zr = 1.711 \text{ \AA}$ was obtained from U. Uhler and L. Akerlund, Arkiv Fysik 10, 431 (1955). The three principal moments of inertia are: $I_A = 1.03083 \times 10^{-38}$, $I_B = 3.8828 \times 10^{-39}$, $I_C = 1.41809 \times 10^{-38}$ g. cm.²

TUNGSTEN OXIDE (WO_{2.72}) (CRYSTAL) OPW = 227.3684

ΔH_f⁰ = Unknown
ΔH_f⁰_{298.15} = -186.70 ± 0.5 kcal/mol

S_{298.15}⁰ = [16.35] gibbs/mol

Heat of Formation.

The adopted heat of formation, -186.7 ± 0.5 kcal/mol, is derived from recent equilibrium data which are in excellent agreement; the results are summarized below. In addition R. C. Griffiths, *J. Electrochem. Soc.* **105**, 398 (1958), has measured the heat of combustion to WO₃(c) which yields ΔH_f⁰₂₉₈(WO_{2.72}, c) = -185.4 ± 1 kcal/mol when recalculated with ΔH_f⁰₂₉₈(WO₃, c) = -201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products. The EMF data reported by Ye. I. Gerasimov, I. A. Vasil'eva, T. P. Chusova, V. A. Gaidarikh, and M. A. Timofeeva, *Zh. Fiz. Khim.* **36**, 358 (1962), give the value of -186.89 kcal/mol for the heat of formation at 298° K. R. J. Ackermann and E. G. Rauh, *J. Phys. Chem.* **67**, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600° K, they have derived indirectly from their measurements the heat of formation, -182.2 kcal/mol (corresponding to -187.2 kcal/mol at 298° K, using the JANAP functions).

3. I. A. Vasil'eva, Ye. I. Gerasimov and Yu. P. Simanov, *Zh. Fiz. Khim.* **34**, 1611 (1960)
4. R. C. Griffiths, *J. Electrochem. Soc.* **105**, 418 (1958).

Heat Capacity and Entropy.

The monoclinic unit cell of WO_{2.72} corresponds to W₁₀O₆₉, as shown by the X-ray diffraction studies of A. Magneli, G. Anderson, B. Blomberg and L. Kihlberg, *Anal. Chem.* **24**, 1998 (1952). The tabulated heat capacities of WO_{2.72}(c) were estimated from those of WO₂(c) and WO₃(c), because all three have similar monoclinic structures as identified by Magneli et al.

The entropy (S₂₉₈⁰ = 16.35 eu) was calculated from ΔS₂₉₈⁰ = 7.96 ± 0.09 eu for reaction A, using all JANAP values. The value of ΔS₂₉₈⁰ was derived from the second law analysis of Griffiths' data, loc. cit.

Heat of Formation.
The adopted heat of formation, -196.0 ± 3 kcal/mol, is a weighted average of those derived from equilibrium data, in addition the following results have been reported.
R. C. Griffiths, J. Electrochem. Soc. 105, 398 (1958), has measured the heat of combustion to W₀₃(c), which yields -195.6 kcal/mol when recalculated with ΔH°₂₉₈(W₀₃, c) = -201.46 kcal/mol. This result is less certain because of the incomplete characterization of the final products. R. J. Ackermann and E. O. Raub, J. Phys. Chem. 67, 2596 (1963), have investigated the tungsten-oxygen system by mass effusion, mass spectroscopy, and X-ray diffraction. In the temperature range from 1300° to 1600°K, they have derived indirectly two values of ΔH°(W_{02.90}, c) -190.9 and -188.0 kcal/mol (corresponding to -196.1 and -193.3 kcal/mol, respectively, at 298.15°K, using all JANAF functions).

Heat Capacity and Entropy.

The monoclinic unit cell of W_{02.90} corresponds to W₂₀O₅₉ as shown by the X-ray diffraction studies of A. Magnell, O. Anderson, B. Blomberg and L. Kihlberg, Anal. Chem. 24, 1998 (1952). The tabulated heat capacities and the entropy (S°₂₉₈ = 17.536 eu) were estimated from those of W₀₂(c) and W₀₃(c), because all three have the similar monoclinic structure as identified by Magnell et al.

ΔH^o_C = Unknown

ΔH^o_{298.15} = -199.56 ± 3 kcal/mol

S^o_{298.15} = [17.90] gibbs/mol

Heat of Formation.

The adopted value, ΔH^o₂₉₈ (WO_{2.96}, c) = -199.56 kcal/mol, was obtained by third law treatment of ΔH^o = 191,600 + 54.0 T (cal/mol) in the temperature range from 1300 - 1550°K, using all JANAF functions. The equation for ΔH^o was reported by R. J. Ackermann and E. G. Rauh, J. Phys. Chem. **67**, 2596 (1963), based on studies by mass spectroscopy and x-ray diffraction. In this study ΔH^o was obtained by comparison of the Gibbs energies of sublimation (to gaseous WO₃, WO₂, W₂O₇, W₂O₉ and W₂O₁₂) over the two systems W-WO₂(c) and WO_{2.96}(c); thus WO_{2.96}(c) was related to WO₂(c) through the gaseous species.

J. E. Battles, Ph. D. Thesis, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, (1964), has reported partial pressures of W₂O₉(g) and W₂O₁₂(g) in equilibrium with WO₃ - WO_{2.96}(c). In light of Ackermann and Rauh's observation, the condensed phase was presumed to have the composition of WO_{2.96}(c). The pressure data are in reasonable agreement with the studies of Ackermann and Rauh as summarized below. Values of ΔH^o₂₉₈ for WO_{2.96}(c) derived from the data of Battles are based on the same author's data for W₂O₉(g), and W₂O₁₂(g) in order to relate WO_{2.96} to WO₂ directly.

Investigator	Reaction	Temperature (°K)	ΔH ^o ₂₉₈ (kcal/mol)	3rd law	2nd law	Drift (cal)	ΔH ^o ₂₉₈ (WO _{2.96} , c)* (kcal/mol)
1. Ackermann & Rauh	A	1300-1550	60.82	56.32	3.2 ± 0.6	-199.57	
2. Ackermann & Rauh	B	1300-1550	41.37	38.35	2.094 ± 0.09	-199.58	
3. Battles	B	1274-1418	40.82	43.28	-1.854 ± 0.05	-199.72	
4. Ackermann & Rauh	C	1300-1550	35.81	33.58	1.551 ± 0.09	-199.60	
5. Battles	C	1333-1418	35.37	38.74	-2.461 ± 0.1	-199.95	

Reaction: A: WO_{2.96}(c) = 0.44 W₂O₉(g) + 0.04 W₂O₁₂(g)

B: WO_{2.96}(c) = 0.29333 W₂O₉(g) + 0.04 W₂O₁₂(g)

C: WO_{2.96}(c) = 0.22 W₂O₁₂(g) + 0.04 W₂O₉(g)

* Third law value adopted in calculation.

Heat Capacity and Entropy.

The tabulated heat capacities and the entropy at 298.15°K were estimated from those of WO₂(c) and WO₃(c). Ackermann and Rauh, loc. cit., have found that the composition WO_{2.96} probably represents the azeotropic composition of the WO₃-x solid solution and is the only single phase which evaporates congruently below 1550°K.

Heat of Formation

P. Glöckner, E. Wassmuth, and L. A. Schryver, Z. phys. Chem. 158, 297 (1932), measured ΔE for the reaction O₃(g) → 3/2 O₂(g) in a calorimeter calibrated by means of the reaction CO(g) + 1/2 O₂(g) → CO₂(g), and found the ratio of the ΔE values for these reactions to be 0.5077 ± 0.0024. The temperature of the experiments is not reported and is assumed to have been 18°C. From the above ratio, ΔH_f^o 298.15 is calculated to be 33.89 ± 0.36 cal. mole⁻¹. A. Kailan and S. Jahn, Z. anorg. Chem. 88, 243 (1910), measured ΔH at an unspecified temperature for the reaction O₃(g) → 3/2 O₂(g) in an electrically calibrated calorimeter. If the temperature of the experiments is assumed to have been 18°C and the modern joule-calorie conversion factor is used, ΔH_f^o 298.15 is found to be 34.3 ± 0.6 kcal. mole⁻¹. Variability in the O₃ content of the feed gas is allowed for in the uncertainty. The value adopted here is 34.2 ± 0.4 kcal. mole⁻¹.

Heat Capacity and Entropy

J. S. Gordon, private communication, April, 1961, has calculated the thermodynamic functions from 298.15° to 6000°K by the method of R. E. Pennington and K. A. Kobe, J. Chem. Phys. 22, 1442 (1954), which takes vibration-rotation interaction and anharmonicity into account. Gordon's data are from L. Pierce, J. Chem. Phys. 24, 139 (1956). The functions below 298.15°K have been calculated for a rigidly rotating harmonic oscillator.

Heat of Formation.

The heat of the reaction PbO (red) + SiO₂ → PbSiO₃ (c) was reported by K. K. Kelley, U. S. Bureau of Mines, Report Investigation 5901 (1962). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAP values for PbO (c) (March 31, 1962) and for SiO₂ (c) (Dec. 31, 1962). The above ΔH_f⁰ = -3.75 ± 0.12 kcal. mole⁻¹.

Heat Capacity and Entropy.

In the low temperature region (53.25-298.15°K.) the C_p values are those determined by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). Above 298.15 C_p values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.25°K. using the Debye and Einstein functions D($\frac{h\nu}{kT}$) + E($\frac{h\nu}{kT}$) + 2E($\frac{h\nu}{kT}$) + E($\frac{h\nu}{kT}$) given by E. G. King, J. Am. Chem. Soc. 81, 799-800 (1959). The S_{53.25} = 3.682 cal. deg. mole⁻¹.

Melting Data.

T_m was taken from Oeller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

June 30, 1965

Heat of Formation

The heat of formation was calculated from the reaction SO₂ + 1/2 O₂ → SO₃ for which three sets of equilibrium constants are available. A summary of the second and third law treatment of the data is given below.

Ref.	Temp. Range	Points	2nd law		3rd law		Drift

References

1. G. B. Taylor and S. Lehnner, Z. Physik. Chem. **B30**, (1931).
2. M. Bodenstein and W. Pohl, Z. Elektrochem. **11**, 373 (1905).
3. A. P. Kapustinaky and L. M. Shumovskiy, Acta Physicochem. URSS **4**, 791 (1956).
4. Combination of above references, with one point omitted due to failure of a statistical test.

The combined set was adopted though it appears that the three sets are not in excellent agreement, and the combination heavily favors Ref. 2. Although there is a definite trend in all the data it cannot be considered definitive enough for use in the modification of the SO₃ functions.

Heat Capacity and Entropy

The bond length and angles were taken from the electron diffraction data of K. J. Palmer, J. Am. Chem. Soc. **50**, 2360 (1938). The vibrational frequencies were taken from the infrared studies of R. W. Lovejoy, J. H. Colwell, D. F. Eggers and G. D. Halsey, J. Chem. Phys. **36**, 612 (1962), which are in excellent accord with those of R. Bent and W. R. Laidner, Spectrochim. Acta **19**, 931 (1963) using different techniques. These values differ from the assignment used by W. Stockmayer, G. M. Kavanagh and H. S. Mickley, J. Chem. Phys. **12**, 408 (1944) in their analysis of the thermodynamic properties of SO₃.

The individual moments of inertia were I_A=I_B = 8.148 X 10⁻³⁹ g. cm.² and I_C = 16.296 X 10⁻³⁹ g. cm.²

DITITANIUM TRIOXIDE (Ti_2O_3)

(CRYSTAL)

GFW = 143.7982

$S^\circ_{298.15} = 18.83$ gibbs/mol	$\Delta H^\circ_{298.15} = -361.50 \pm 2$ kcal/mol	$\Delta H^\circ_{298.15} = -363.49 \pm 2$ kcal/mol
$T_f = 473^\circ\text{K}$	$\Delta H^\circ_f = 0.215$ kcal/mol	
$T_m = 2112^\circ\text{K}$	$\Delta H^\circ_m = [26.4]$ kcal/mol	

Heat of Formation

G. L. Humphrey, J. Am. Chem. Soc. 73, 1887 (1951), determined the enthalpy change $\Delta H^\circ_{298} = -88.11 \pm 0.1$ kcal/mol for the reaction $\text{Ti}_2\text{O}_3(\text{c}) + 1/2\text{O}_2(\text{g}) = 2\text{TiO}_2(\text{rutile})$ using bomb calorimetry. Based on this result and $\Delta H^\circ_{298}(\text{rutile}) = -225.8$ kcal/mol, the adopted value of ΔH°_{298} for $\text{Ti}_2\text{O}_3(\text{c})$ is calculated to be -363.49 ± 2 kcal/mol. A value of $\Delta H^\circ_{298}(\text{Ti}_2\text{O}_3, \text{c}) = -362.8 \pm 0.6$ kcal/mol was reported by S. M. Ariya, M. P. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (English transl.) 2, 16 (1957), who measured the heat of combustion of various compositions in the Ti_2O_3 system. Ariya et al. used an estimated correction for the formation of TiO_{2-x} , while Humphrey obtained values of 0.1 - 1.3 kcal/mol by grinding the product and returning it with white oil. Most of the assigned uncertainty arises from this problem. [See $\text{TiO}_2(\text{rutile})$ for further details.]

Heat Capacity and Entropy

The low temperature heat capacities, 53 - 296°K, were measured by C. H. Shonate, J. Am. Chem. Soc. 68, 310 (1946). The data indicate a small anomaly in Cp near 240°K. High temperature enthalpies, 375 - 1750°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by drop calorimetry. The heat capacities, 298 - 473°K, derived by Naylor, loc. cit., are joined smoothly with the low temperature Cp at 298°K. Cp values above 473°K are calculated from the heat capacity equation for the β phase derived by Naylor.

S. Nomura, T. Kawakubo, and T. Yanagi, J. Phys. Soc. Japan, 16, 706 (1961), measured the specific heat in the range 70 - 250°K with a conduction-type calorimeter. A broad anomaly in the specific heat was observed from 160 to 200°K. Below this region the Cp values are unreasonably small, but near 200°K the data are closer to the adopted values.

The S°_{298} is calculated from the adopted low temperature Cp based on $S^\circ_{50} = 0.442$ eu. A. D. Pearson, J. Phys. Chem. Solids, 5, 316 (1958), studied the crystal structure of Ti_2O_3 by X-ray method and found that the agreement between calculated and observed density values is good; in other words, there are no significant vacant sites in Ti_2O_3 crystal lattice. This was later confirmed by S. C. Abrahams, Phys. Rev. 130, 2230 (1963). Therefore we do not add vacancy entropy to S°_{298} . Because of the magnetic transition ($\alpha \rightarrow \beta$) at 473°K, we have assumed that no spin-magnetic entropy is likely below 50°K. See Transition Data for more information.

Transition Data

Tf and ΔH°_f were obtained from B. F. Naylor, loc. cit. S. Nomura, T. Kawakubo and T. Yanagi, J. Phys. Soc. Japan 16, 706 (1961), derived the much smaller $\Delta H^\circ_f = 0.036$ kcal/mol from their observations with a conduction-type calorimeter. These authors suggested that the discrepancy may be due to non-stoichiometry on to impurities in the sample studied by Naylor.

Single-crystal neutron diffraction studied by S. C. Abrahams, Phys. Rev. 130, 2230 (1963), indicate that Ti_2O_3 undergoes an antiferromagnetic ordering of small magnetic moment, associated with the Ti^{3+} cations, below a Neel temperature of about 660°K. The temperature of this transition has been reported variously as about 450 to 600°K based on other properties. A. D. Pearson, J. Phys. Chem. Solids 5, 316 (1958), found no change in the Ti_2O_3 corundum-type structure, but noted a rapid change in the lattice parameters between 430 and 473°K. Observations of corresponding changes in magnetic susceptibility, resistivity and thermoelectric power have been summarized by the same authors and by J. B. Goodenough, Phys. Rev. 117, 1442 (1960). Goodenough attempted to interpret the earlier observations in terms of strong cation-cation interactions.

The magnetic nature of the transition suggests that any spin-magnetic entropy in Ti_2O_3 would be included in ΔH°_f and in the observed Cp values for α and β phases. Magnetic contributions are thus unlikely below 50°K.

Melting Data

See Ti_2O_3 table for details.

DITITANIUM TRIOXIDE (Ti₂O₃)

(LIQUID)

S°_{298.15} = [22.952] gibbs/mol

Tm = 2112 ± 10°K

ΔH°_{298.15} = [-342.087] kcal/mol

ΔHm° = [26.4] kcal/mol

Heat of Formation

The heat of formation, ΔH°₂₉₈, for Ti₂O₃(l) is obtained from that of the crystal by adding ΔHm° and the difference between H°₂₁₁₂ - H°₂₉₈ for Ti₂O₃(c) and Ti₂O₃(l).

Heat Capacity and Entropy

The heat capacity of Ti₂O₃(l) is estimated on the basis of 7.5 gibbs/g-atom. The S°₂₉₈ is derived in a manner analogous to that of the heat of formation.

Melting Data

The adopted Tm was determined by P. G. Wahlbeck and P. W. Gilles, J. Am. Ceram. Soc. **49**, 18 (1966). ΔHm° is estimated based on the assumption that at Tm the entropy of melting is 2.5 eu/g-atom. Other Tm values reported are listed as follows:

June 30, 1962; Mar. 31, 1963; Sept. 30, 1966

 $\Delta H_f^\circ = -200.11 \pm 0.2$ kcal/mol $\Delta H_f^\circ_{298.15} = -201.46 \pm 0.2$ kcal/mol $\Delta H^\circ = 0.355$ kcal/mol $\Delta H_m^\circ = 17.55$ kcal/mol $\Delta H_f^\circ_{298.15}$ (to monomer) = 131.46 kcal/mol $\Delta H_f^\circ_{298.15}$ (to dimer) = 82.36 kcal/mol $\Delta H_f^\circ_{298.15}$ (to trimer) = 40.26 kcal/mol $\Delta H_f^\circ_{298.15}$ (to tetramer) = 33.91 kcal/mol

Heat of Formation.

The selected heat of formation, $\Delta H_f^\circ_{298}(\text{WO}_3, c) = -201.46 \pm 0.2$ kcal/mol, was determined by A. D. Meh, J. Am. Chem. Soc. **81**, 1582 (1959), using bomb calorimetry. G. Huff, E. Squitieri and P. E. Snyder, J. Am. Chem. Soc. **70**, 3380 (1948), have reviewed the literature heat of formation data and also measured calorimetrically the heat of formation, -201.84 ± 0.1 kcal/mol, which is in good agreement with the value selected. Other combustion values were reported as $\Delta H_f^\circ_{298} = -199 \pm 1$ kcal/mol by R. C. Griffiths, J. Electrochem. Soc. **105**, 398 (1958); and $\Delta H_f^\circ_{298} = -205.3$ kcal/mol by I. A. Vasil'eva, V. I. Gerasimov, and Y. P. Simanov, Zh. Fiz. Khim. **31**, 882 (1957). R. C. Griffiths, J. Electrochem. Soc. **106**, 418 (1959), also derived the heat of formation, -202.8 ± 1.4 kcal/mol from equilibrium data.

Heat Capacity and Entropy.

The low temperature (53-296.7°K) heat capacities and high temperature (399.6 - 1835.8°K) enthalpy changes have been measured by E. G. King, W. W. Kellner, and A. U. Christensen, U.S. Bur. Mines R.I. 5664 (1960); and these data have been used to derive the tabulated heat capacities. Low temperature and high temperature values were joined smoothly at 298.15°K. The entropy was calculated from the heat capacities based on $S^\circ_1 = 1.31$ eu.

King et al. were apparently unaware of the transition near 593°K which was reported by J. A. Perri, E. Banks, and B. Post, J. Appl. Phys. **28**, 1272 (1957), and they did not take sufficient points in that region to fix the precise enthalpy curve. We have adopted only one curve through the region because of the insufficiency of the data and also because the heat effects appear to be small or gradual.

Transition and Melting Data.

The heat of transition, the transition point, the heat of melting and the melting point were derived from the high temperature enthalpy data of King et al., loc. cit.

The melting point, $1746 \pm 1^\circ\text{K}$, has also been quoted by S. J. Schneider, NBS Monograph **68**, "Compilation of the Melting Points of the Metal Oxides," October 10, 1963.

In the high temperature X-ray diffractometric studies, Perri et al., loc. cit., indicate that WO_3 undergoes a phase transition from monoclinic to orthorhombic at approximately 593°K and from orthorhombic to tetragonal at 993°K.

Heat of Sublimation.

The values of ΔH_s° at 298.15°K are calculated as the heat of sublimation of one mole of crystal to one mole of monomer, 1/2 mole of dimer, 1/3 mole of trimer and 1/4 mole of tetramer, respectively.

$\Delta H_f^\circ 0 = -327.3 \pm 3.5 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -329.3 \pm 3.5 \text{ kcal. mole}^{-1}$
 $S_{298.15}^\circ = 44.654 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_m = 1016^\circ\text{K.}$

Heat of Formation.

The heat of the reaction $2\text{PbO}(c) + \text{SiO}_2(c) \rightarrow \text{Pb}_2\text{SiO}_4(c)$ was reported by O. Kubaschewski and E. L. Evans, Metallurgical Thermochemistry, Pergamon Press, New York (1958). This value for the heat of reaction of the oxides has been converted to the heat of formation using JANAF values for $\text{PbO}(c)$ (March 31, 1962) and for $\text{SiO}_2(c)$ (Dec. 31, 1962). The above $\Delta H_f^\circ 298.15 = -7.00 \pm 3.5 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

In the low temperature region (53.07 - 298.15°K.) the C_p values are those determined by E. O. King, J. Am. Chem. Soc., 81, 799-800 (1959). Above 298.15°K. values were estimated by summing the values for the constituent oxides and graphically smoothing these into the low temperature measurements. The entropy was calculated at 53.07°K. using the Debye and Einstein functions $D(\frac{h\nu}{kT}) + 2E(\frac{h\nu}{kT}) + E(\frac{h\nu}{kT})$ given by E. O. King, J. Am. Chem. Soc., 81, 799-800 (1959). The $S_{53.07}^\circ = 8.248 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

T_m was taken from Geller, Creamer and Bunting, J. Research Natl. Bureau of Standards, 13, 237 (1934).

Trilead Tetroxide (Pb_3O_4)
(Crystal) Mol. Wt. = 685.63

ZIRCONIUM ORTHOSILICATE ($ZrSiO_4$) (CRYSTAL)

$\Delta H_f^\circ = -481.1 \pm 0.7 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = -483.7 \pm 0.7 \text{ kcal. mole}^{-1}$
 $T_d = 1811^\circ K.$

ZIRCONIUM ORTHOSILICATE ($ZrSiO_4$)

$S_{298.15}^\circ = 20.083 \pm 0.3 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$
 $T_d = 1811^\circ K.$

Heat of Formation.
 The $\Delta H_f^\circ 298.15$ was calculated from the $\Delta H_f^\circ 298.15$ of its constituent oxides $ZrO_2(c) + SiO_2(c) = ZrSiO_4(c)$ and from the $\Delta H_f^\circ 298.15$ of $ZrO_2(c)$ (June 30, 1961) and $SiO_2(c)$ (Dec. 31, 1962) in JANAP tables. The $\Delta H_f^\circ 298.15 = -4.736 \text{ kcal. mole}^{-1}$ was based on the free energy of formation of its constituent oxides at the decomposition temperature $1811^\circ K.$

Heat Capacity and Entropy.
 At low temperatures C_p were used from K. K. Kelley, J. Am. Chem. Soc. 63, 2750 (1941). From $298-940^\circ K.$ C_p was calculated by using the J. P. Coughlin and E. O. King equation $C_p = 31.48 + 3.92 \times 10^{-5} T - 8.08 \times 10^{-9} T^2$, J. Am. Chem. Soc., 72, 2262 (1950), which joined smoothly with the low temperature data. Above $940^\circ K.$ the data was estimated by extending the curve smoothly. The entropy was calculated at $52.7^\circ K.$ using the Debye and Einstein functions $D(\frac{h\nu}{kT}) + 28(\frac{h\nu}{kT}) + 28(\frac{h\nu}{kT}) + E(\frac{12\pi^2}{h\nu})$ given by K. K. Kelley, J. Am. Chem. Soc., 63, 2750 (1941). $S_{52.7}^\circ = 0.65404 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Temperature of Decomposition.
 T_d is the temperature at which $\Delta F_T^\circ = 0$ for the reaction $ZrSiO_4(c) \rightarrow ZrO_2(c) + SiO_2(c)$. $T_d = 1811^\circ K.$ was taken from C. E. Curtis and H. G. Sowaan, J. Am. Soc., 36, 190 (1953).

TRITITANIUM PENTOXIDE, ALPHA (α -Ti₃O₅)

(CRYSTAL)

QPM = 223.697

$\Delta H_f^\circ = -584.63 \pm 0.7$ kcal/mol
 $\Delta H_f^\circ_{298.15} = -587.75 \pm 3.0$ kcal/mol
 $\Delta H_f^\circ = [2.81]$ kcal/mol

$S^\circ_{298.15} = 30.935$ gibbs/mol
 $T_f = 450^\circ\text{K}$

Heat of Formation

The enthalpy change, $\Delta H^\circ_{298} = -49.65 \pm 0.05$ kcal/mol, for the reaction $\text{Ti}_3\text{O}_5(\text{c}) + 1/2 \text{O}_2(\text{g}) = 3 \text{TiO}_2(\text{rutile})$ has been measured by G. L. Humphrey, J. Am. Chem. Soc. 73, 1587 (1951), using combustion bomb calorimetry. Based on the reported ΔH°_{298} and $\Delta H^\circ_{298}(\text{rutile}) = -225.8$ kcal/mol, the value of ΔH°_{298} for $\text{Ti}_3\text{O}_5(\text{a})$ is derived as -587.75 ± 0.7 kcal/mol. A value of -587.0 ± 1.0 kcal/mol was obtained by S. M. Araya, M. F. Morozova, and E. Vol'f, Russ. J. Inorg. Chem. (English transl.) 2, 16 (1957), from a similar calorimetric study on Ti-O compounds of various compositions. The latter authors observed that their combustion product had a composition of about $\text{Ti}_{1.99}\text{O}_5$ so they applied an approximate correction to their data. Presumably, the rutile in Humphrey's combustion was also deficient in oxygen, but we have not attempted to make a correction (see TiO_2 (rutile) table for further details).

Heat Capacity and Entropy

Low temperature heat capacities, 53.1 - 296.6°K, were measured by C. H. Shomate, J. Am. Chem. Soc. 68, 310 (1946). High temperature enthalpies, 350.5 - 1340°K, were determined by B. F. Naylor, J. Am. Chem. Soc. 68, 1077 (1946), by use of drop calorimetry. The heat capacities, 298 - 450°K, derived by Naylor are too high to join smoothly at 298°K with the low temperature data, hence they are not used. The Cp values above 296.6°K are obtained by graphical extrapolation of the adopted low temperature Cp.

The samples used by both Shomate and Naylor were prepared by reduction of titanium dioxide with carbon at 1350°C. Analysis of the product gave 99.1% Ti_3O_5 , 0.2% TiO and 0.7% SiO_2 . X-ray lines from the sample were weak and fuzzy but no data were given. Thus comparison with subsequent studies is not possible. According to Naylor, the enthalpy measurements showed a transition at about 450°K. When Ti_3O_5 was heated above this temperature, it did not return to the original state on cooling. Enthalpies were then systematically higher by up to 10 percent. The change in the enthalpy curve seemed to depend upon both the temperature and time of heating above Tt. Regrinding was the only method found for returning the sample to its original state. Possible explanations are presented in the Transition Data.

S°_{298} is calculated from $S^\circ_{50} = 0.88$ eu using the low temperature Cp reported by Shomate, loc. cit. It is pertinent to ask if there should be entropy contributions due to vacancies in the crystal lattice or to spin-magnetic effects below 50°K. S. Asbrink and A. Magnelli, Acta Cryst. 12, 575 (1959), showed that the X-ray crystallographic density is greater than the experimental density by less than 1%, thus the entropy due to the presence of vacancies is considered to be negligible. We also assume that any spin-magnetic entropy is related to the $\alpha \rightarrow \beta$ transition, by analogy with the $\alpha \rightarrow \beta$ transition of Ti_2O_3 . Consistent with this assumption is the observation that the entropy of $\beta\text{-Ti}_3\text{O}_5$ is already larger than the sum of entropies for $\beta\text{-Ti}_2\text{O}_3$ and TiO_2 .

Transition Data

See $\text{Ti}_3\text{O}_5(\beta)$ table.

TRITITANIUM PENTOXIDE, BETA (β -Ti₃O₅) (CRYSTAL)

OPW = 223.697

ΔH°_{298.15} = [-585.354] kcal/mol

ΔH° = [2.81] kcal/mol

ΔH° = [33] kcal/mol

T_g = 450°K

T_m = 2047 ± 10°K

S°_{298.15} = [35.913] gibbs/mol

Heat of Formation

The value of ΔH°₂₉₈(β) is obtained from ΔH°₂₉₈(α) by adding ΔH° and the difference between H°₄₅₀ - H°₂₉₈ for Ti₃O₅(α) and Ti₃O₅(β).

Heat Capacity and Entropy

The heat capacities are derived from the enthalpy data, 452 - 1340°K, measured by B. P. Naylor, J. Am. Chem. Soc. 69, 1077 (1946). The Cp values beyond the experimental range are obtained by linear extrapolation.

The S°₂₉₈ is calculated in a manner analogous to that of the heat of formation. For a discussion pertaining to the entropy uncertainty, see the Transition Data.

Transition Data

Tt and ΔH° are based on the β-phase enthalpy data of Naylor, loc. cit., and on the selected enthalpies of the α-phase. ΔH° is thus subject to an unknown error since the β-phase enthalpies correspond to a somewhat different state than do the α-phase values (see α-Ti₃O₅). The enthalpy data also show unusual scatter in the range 452-530°K. Because of these uncertainties, the more recent X-ray studies are summarized below.

S. Abrink and A. Magnelli, *Acta Cryst.* 16, 575 (1959), found that monoclinic α-Ti₃O₅ transforms to a β form of the anosovite type (slightly deformed pseudo-brookite) at about 393°K, i. e., over 50° lower than Naylor's value. P. O. Wahlbeck and P. W. Gilles, *J. Am. Ceram. Soc.* 49, 180 (1966), confirmed that the transition occurs between 373 and 473°K but did not measure the temperature accurately. In both studies only the α form was observed on cooling the samples to room temperature. Abrink and Magnelli noted the following in X-ray studies at elevated temperatures. In a wide region around 393°K, the powder reflections of the unstable phase disappeared, while the general characteristics of the stable one formed within considerably less than one hour. Complete development of some reflections of the stable phase took several hours, while some lines appeared with anomalous intensities at temperatures approaching the transformation point, thus "foreshadowing" the change of structure. Small contents of Fe or Mg stabilized the β form at room temperature.

These observations suggest that the transformation may be considered as a "perit" which occurs over a range of temperatures. The anomalous enthalpy data observed by Naylor may arise from slow completion of the transition and from stabilization of part of the sample in the β form due to impurities. The latter suggestion is consistent with Naylor's observation that regrounding returned the sample to its normal α form. Correction of the enthalpy data based on these assumptions does not appear practical. Pending new data for a well-characterized sample, we must rely on the results of Naylor.

Melting Data.

P. O. Wahlbeck and P. W. Gilles, *J. Am. Ceram. Soc.* 49, 180 (1966), found that Ti₃O₅ melts incongruently at 2047 ± 10°K which is adopted. ΔH° is estimated assuming that at T_m the entropy of melting is 2 eu/g-atom. Melting points of 2173 and 1983°K were reported by R. DeVries and R. Roy, *Bull. Am. Ceram. Soc.* 33, 370 (1954), and O. Bräuer and W. Litke, *J. Inorg. Nucl. Chem.* 16, 67 (1960), respectively.

TRITITANIUM PENTOXIDE (Ti₃O₅) (LIQUID)S_{298.15}^o = [39.679] gibbs/molT_m = 2047 ± 10°KΔH_{298.15}^o = [-560.754] kcal/molΔH_m^o = [33] kcal/mol

OPW = 223.697

Heat of Formation

The ΔH_{298.15(1)}^o is obtained from ΔH_{298.15(β)}^o by adding ΔH_m^o and the difference between H₂O₄₇^o - H₂^o₂₉₈ for Ti₃O₅(β) and Ti₃O₅(1).

Heat Capacity and Entropy

The heat capacity is estimated on the basis of 7.0 gibbs/g-atom. S₂₉₈^o is obtained in a manner analogous to that of the heat of formation.

Melting Data

See Ti₃O₅(β) table for details.

DIPHOSPHORUS TRIOXIDE, DIMERIC (P₂O₅) (Ideal gas)

Mol. Wt. = 219.90

ΔH_f^o 298.15 = -512.5 ± 8 kcal. mole⁻¹

S_{298.15}^o = 82.6 cal. deg⁻¹ mole⁻¹

Point group = T_d

Vibrational Frequencies and Degeneracies

ω cm ⁻¹	ω cm ⁻¹
613 (1)	465 (2)
613 (1)	643 (3)
302 (3)	919 (3)
370 (3)	1029 (2)
407 (3)	636 (3)

Bond Lengths and Angles: P-O distance = 1.65 ± 0.02 Å

P-O-P angle = 127.5 ± 1.0° O-P-O angle = 99° ± 1° O'' = 12

Product of Moments of Inertia: I_AI_BI_C = 4.832 X 10⁻¹¹² g.³ cm.⁶

Heat of Formation. ΔH_f^o 298.15 for liquid P₂O₅ was measured by W. E. Koerner and F. Daniels, J. Chem. Phys. 20, 113 (1952). The measurement was made by burning samples of red phosphorus in nitric oxide in a flow calorimeter. Calculation of the heat of formation of the gas was made using ΔH_v^o 298.15 = 11.46 kcal. mole⁻¹ as reported by T. D. Farr, Tenn. Valley Authority, Chem. Engr. Report No. 8 (1950).

Heat Capacity and Entropy. The vibrational levels are from the Raman data of H. Gerding, H. van Bredede and H. C. J. de Decker, Rec. Trav. Chim. 61, 549 (1942), and infra-red spectra data of T. A. Sidorov and N. N. Sobolev, Optics and Spect. 2, 710 (1957). Bond lengths and angles are from electron diffraction data by G. C. Hampson and A. J. Stosick, J. Am. Chem. Soc. 80, 1814 (1958).

Product of the Moments of Inertia: I_AI_BI_C = [5.917 × 10⁻¹¹²] g³ cm⁶ σ = [4]

Heat of Formation.

The adopted value, ΔH°₂₉₈ (W₂O₃, g) = -278.2 kcal/mol, was reduced from ΔH°_{f,450} = -272.5 kcal/mol, reported by R. J. Ackermann and E. G. Hauh, J. Phys. Chem. 67, 2596 (1963). They have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1800°K by mass spectrometry, mass effusion, and X-ray diffraction, and also have determined ΔH°_f (W₂O₃, g) = -272.500 ± 54.987 (cal/mol) from partial pressure measurements over the W-W₂O₃(c) system.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide," The Ohio State University, 1964, has also studied the same system in the temperature range from 1418 to 1527° K. Third law calculation of the partial pressure data gives ΔH°₂₉₈ = 144.0 kcal/mol for 3 W₂O₃(c) = W₂O₃(g) + W(c) which yields ΔH°₂₉₈ (W₂O₃, g) = -278.8 kcal/mol, using all JANAF functions. This value is in good agreement with the value adopted.

J. H. Norman and H. G. Staley, J. Chem. Phys. 43, 3804 (1965), have obtained ΔH°_{f,1800} = -127 kcal/mol for 2 W₂O₃(g) = W₂O₃(g) by mass spectrometric study of the vapor over W₂O₃ dissolved in CaO-Al₂O₃-SiO₂. The value of ΔH°_f was determined by the second law method from ion intensities and leads to ΔH°_{f,298} (W₂O₃, g) = -275 kcal/mol, using all JANAF functions (dated Sept. 30, 1966). The absolute pressure values reported by Norman and Staley appear to be quite inconsistent with the JANAF functions, since they lead to ΔH°_f (W₂O₃, g) = -246 kcal/mol by the third law method.

Investigator	Chemical Reaction	Temperature (°K)	ΔH° ₂₉₈ (kcal/mol)	Drift (eu)	ΔH° _f (W ₂ O ₃ , g) (kcal/mol)
Ackermann & Hauh	3 W ₂ O ₃ (c) = W ₂ O ₃ (g) + W(c)	1300-1800	144.54	0.01	-278.2*
Battles	3 W ₂ O ₃ (c) = W ₂ O ₃ (g) + W(c)	1418-1527	142.66	0.85 ± 0.40	-278.8*
Norman & Staley	2 W ₂ O ₃ (g) = W ₂ O ₃ (g)	1700-1900	-135	-106	-275 **

* Third law value adopted in calculation.
** Second law value adopted in calculation.

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 600 cm⁻¹ (4), 300 cm⁻¹ (8), and 1721 cm⁻¹ (6) in order to give the entropy at 1450°K, S₁₄₅₀ = 164.66 eu, corresponding to ΔS_{f,1450} = 54.98 eu which was reported by Ackermann and Hauh. The adopted value, S°₂₉₈ (W₂O₃, g) = 99.3 eu, was reduced from the entropy at 1450°K, using JANAF functions. Second law calculation of the partial pressure data of Battles gives ΔS°_{f,1470} = 63.5 eu for 3 W₂O₃(c) = W₂O₃(g) + W(c). This yields S°₂₉₈ (W₂O₃, g) = 97.9 eu.

The molecular configuration for W₂O₃(g) was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atom, and two of these tetrahedra share a common oxygen edge to form a planar four-member ring. The bond distance W-O was estimated as 1.81 Å and the bond angle O-W-O = 109.47° and W-O_{bridge}-W = 70.53°. The three principal moments of inertia are: I_A = 3.481 × 10⁻³⁷, I_B = 1.363 × 10⁻³⁷ and I_C = 1.247 × 10⁻³⁷ g cm².

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47°]

Product of the Moments of Inertia: $I_A I_B I_C = [7.65 \times 10^{-111}] \text{ g}^3 \text{ cm}^6$

$\sigma = [4]$

Heat of Formation.

R. J. Ackermann and E. G. Rauh, J. Phys. Chem. 67, 2586 (1963), have studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and X-ray diffraction, and also have determined the $\Delta H_f^\circ(W_3O_8, g) = -400,900 \pm 9054$ T (cal/mol) from partial pressure measurements over W-WO₂ (c). The adopted value, $\Delta H_f^\circ(W_3O_8, g) = -408.7$ kcal/mol, was reduced from $\Delta H_f^\circ(W_3O_8, g) = -400.9$ kcal/mol, using JANAF functions.

Investigator	Chemical Reaction	Temperature (°K)	ΔH_f° (kcal/mol)	Drift (eu)	ΔH_f° (W_3O_8, g) (kcal/mol)
Ackermann & Rauh	4 WO ₂ (c) = W ₃ O ₈ (g)+W(c)	1300-1600*	155.05	155.09	-408.7
		2nd law	155.05		
		3rd law			

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm⁻¹ (6), 350 cm⁻¹ (4), 242 cm⁻¹ (8), 199 cm⁻¹ (3) and 150 cm⁻¹ (6) in order to give the entropy at 1450°K, $S_{1450}^\circ = 208.18$ eu, corresponding to $\Delta H_f^\circ = -90.54$ eu, which was reported by Ackermann and Rauh.

The molecular configuration for W₃O₈(g) was estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, the three tetrahedra are connected by two common edges, and also the three tungsten atoms are in the same axis. The bond distance W-O was estimated as 1.81 Å and the bond angle $\angle OWO = 109.47^\circ$. The three principal moments of inertia are: $I_A = I_B = 4.060 \times 10^{-37}$ and $I_C = 4.641 \times 10^{-38} \text{ g cm}^2$.

$\sigma = [6]$

Heat of Formation.

The adopted value, $\Delta H_{298}^\circ(\text{WO}_3\text{g}) = -483.6 \text{ kcal/mol}$, was reduced from $\Delta H_{1450}^\circ(\text{WO}_3\text{g}) = -474.1 \text{ kcal/mol}$ of R. J. Ackermann and E. G. Reau, *J. Phys. Chem.* **67**, 2598 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600 °K by mass spectrometry, mass effusion, and X-ray diffraction, and determined $\Delta H^\circ(\text{WO}_3\text{g}) = -474.100 \pm 110.267 \text{ (cal/mol)}$ from partial pressure measurements over W-WO₂(c). They reviewed the previous determinations 1, 2, 3, 4 of the thermodynamic properties of sublimation of WO₃, and also pointed out that it was not possible to make quantitative observations on stoichiometric WO₃ in vacuo, since it is a "bivalent" system and the ion current is not constant until the composition of the sample reaches WO_{2.96}. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of W₂O₅(g) over W-WO₂(c) in the temperature range from 1399° to 1527°K. Third law calculation of the partial pressure data gives $\Delta H_{298}^\circ = -148.2 \text{ kcal/mol}$ for $4.5 \text{ WO}_2(\text{c}) = \text{W}_2\text{O}_5(\text{c}) + 1.5 \text{ W}(\text{c})$, which yields $\Delta H_{298}^\circ(\text{WO}_3\text{g}) = -486.0 \text{ kcal/mol}$, using all JANAF functions.

J. H. Norman and H. G. Staley, *J. Chem. Phys.* **43**, 3904 (1965), have obtained $\Delta H_{1600}^\circ = -240 \text{ kcal/mol}$ for $3 \text{ WO}_2(\text{c}) = \text{W}_2\text{O}_5(\text{c})$ by mass spectrometric study of the vapor over WO₃ dissolved in CaO-Al₂O₃-SiO₂. The value of ΔH° was determined by the second law method from ion intensities and leads to $\Delta H_{298}^\circ(\text{WO}_3\text{g}) = -463.4 \text{ kcal/mol}$. Using all JANAF functions (dated September 30, 1966). The absolute pressure values reported by Norman and Staley also appear to be quite inconsistent with the JANAF functions, since they lead to -443 kcal/mol by the third law method.

** Second law value adopted in calculation

Heat Capacity and Entropy.

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1} (6), 396 cm^{-1} (3), 330 cm^{-1} (9), 200 cm^{-1} (6), and 150 cm^{-1} (6) in order to give the entropy at 1450°K , $S_{1450}^\circ = 219.14 \text{ eu}$, corresponding to $\Delta S_{1450}^\circ = 110.28 \text{ eu}$, reported by Ackermann and Reau. The adopted value, $S_{298}^\circ(\text{WO}_3\text{g}) = 120.6 \text{ eu}$, was reduced from the entropy at 1450°K , using JANAF functions. Second law calculation of the partial pressure data of Battles gives $\Delta S_{1455}^\circ = 71.7 \text{ eu}$ for $4.5 \text{ WO}_2(\text{c}) = \text{W}_2\text{O}_5(\text{c}) + 1.5 \text{ W}(\text{c})$. This yields $S_{298}^\circ(\text{WO}_3\text{g}) = 122.4 \text{ eu}$.

The molecular configuration for W₂O₅(g) is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atom, and that each tetrahedron shares two oxygen atoms to form a planar six-member ring. The bond distance W-O is estimated as 1.91 Å and the bond angles O-W-O = 109.47° and W-O-bridge-W = 130.53°. The three principal moments of inertia are: $I_A = I_B = 2.805 \times 10^{-37}$ and $I_C = 4.913 \times 10^{-37} \text{ g cm}^2$.

Heat of Formation.

The heat of formation (ΔH_f° 298.15) of P₄O₁₀(c) has been reported by many investigators. The most recent value, ΔH_f° 298.15 = -719.4 ± 2.0 kcal. mole⁻¹ for the reaction P₄(w, white, c) + 5O₂(g) = P₄O₁₀(hex., c), was determined by E. F. Egan, Jr. and B. B. Luff, "Heats of Formation of Phosphorus Oxides", June 1, 1963 to Nov. 30, 1963, Tennessee Valley Authority, Office of Agriculture and Chemical Development, Fundamental Research Branch, Wilson Dam, Alabama. This ΔH_f° 298.15 value was derived from energy of combustion, ΔE_c = -716.397 kcal. mole⁻¹, which is an average value of many measurements using three different sample forms, i.e. uncoated phosphorus, lucite-coated phosphorus and cellulose acetate-coated phosphorus. The adopted ΔH_f° 298.15 (P₄O₁₀, c) value was recalculated based on the P(red, V, c) as reference state.

The heat of combustion of white phosphorus was determined as -713.2 ± 1.0 kcal. mole⁻¹ by W. S. Holmes, Trans. Paraday Soc. 58, 1916 (1962), yielding ΔH_f° 298.15 (P₄O₁₀, c) = -696.5 ± 1.3 kcal. mole⁻¹, based on P(red, V, c) as reference state. The heat of formation of P₂O₅ from red phosphorus was reported to be -355 ± 2 kcal. mole⁻¹ by W. S. Koerner and P. Daniels, J. Chem. Phys. 20, 115 (1952). The product, P₂O₅, was considered to be a mixture of two forms, i.e. crystalline and amorphous. The other ΔH_f° 298.15 (P₄O₁₀, c) values reported by early investigators were reviewed by Egan and Luff, loc. cit.

Heat Capacity and Entropy.

The heat capacities (18-324°K.) and $S_{298.15}^\circ$ adopted were taken from R. J. L. Andon, J. P. Counsell, R. McKerrell and J. P. Martin, Trans. Faraday Soc. 59, 2702 (1963). The Cp values above 324°K. were obtained by graphical extrapolation. The $S_{298.15}^\circ$ value was calculated based on S_{10}° = 0.35 e.u.

Low temperature (15-310°K.) and high temperature (298.15-623.15°K.) heat capacities were also measured by Thermal Laboratory, The Dow Chemical Company, private communication, June 18, 1962, and M. Prandien, J. Res. Natl. Bur. Std. 10, 35 (1933), respectively. The low temperature data were not adopted because they are less satisfactory than the data of Andon et al. The high temperature data were not used because the sample employed for enthalpy measurements was not explicitly reported as pure hexagonal form.

Sublimation Data.

The value of ΔH_g° 298.15 was derived from the vapor pressure data by both the second and third law analyses. See the P₄O₁₀(g) table for details. T_g is the temperature at which the free energy change of the reaction P₄O₁₀(hex. c) = P₄O₁₀(g) approaches zero. Sublimation temperature for P₄O₁₀(c) was derived to be 532°K., 636°K. (average of three determinations) and 623.7°K. (average of two determinations) by M. Prandien, loc. cit. from the vapor pressure data reported by J. M. Hoeflake and M. P. Schaffer, Rec. trav. chim. 45, 191 (1926); A. Saite, Z. physik. Chem. 149, 337 (1930); and A. Saite and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924), respectively.

Heat of Formation.

The value of ΔH_f^0 298.15 (P₂O₅, g) was calculated from the heats of formation and sublimation for P₂O₅ (hex., c). The heat of sublimation (ΔH_s^0 298.15) was derived from vapor pressure data by the second and third law methods. The results obtained are presented as follows.

Investigator	Temperature, °K	Second Law Value	Third Law Value	Drift, e.u.

1. J. W. A. Hoeflake and P. E. C. Schaffer, Rec. trav. chim. 45, 191 (1926).

2. J. C. Southard and R. A. Nelson, J. Am. Chem. Soc. 59, 911 (1937).

The value of ΔH_f^0 298.15 adopted was 25.34 ± 0.08 kcal. mole⁻¹. There are many vapor pressure measurements reported but only the above two over P₂O₅ (hex., c).

It has been shown that P₂O₅ has three solid phases and two liquid phases. The three solid phases are hexagonal, orthorhombic and tetragonal. As temperature increases, the thermal stability of P₂O₅ follows the same order. The metastable liquid, according to data of Hoeflake and Schaffer, loc. cit., is from hexagonal form. The stable liquid is from tetragonal form. W. L. Hill, G. T. Faust and S. B. Hendricks, J. Am. Chem. Soc. 65, 794 (1943) reported that molecules of P₂O₅ having the same structure as in the vapor are present in the hexagonal form of the solid. The vapor pressures of P₂O₅ over different condensed phases have been measured by many investigators and reviewed by T. D. Farr, "Phosphorus, Properties of the Elements and Some of Its Compounds", Tennessee Valley Authority, Wilson Dam, Alabama, 1950. The complexity of the solid state of P₂O₅ has also been discussed by A. Seitz and A. J. Rutgers, J. Chem. Soc. 125, 2573 (1924); A. Seitz, Z. physik. Chem. A149, 337 (1930); A. Smits, J. A. A. Ketselaar and J. L. Meyerling, *ibid.*, B41, 87 (1938); and A. Seitz, *ibid.*, B46, 43 (1940).

Heat Capacity and Entropy.

The molecular structure and constants were obtained from P. A. Akishin, N. G. Rambidi and E. Z. Zaslavin, Kristallografiya, 3, 360 (1959). The molecular structure of P₂O₅ (g) has also been studied by the electron diffraction method by L. R. Maxwell, S. B. Hendricks and L. S. Deming, J. Chem. Phys. 5, 626 (1937), and G. C. Hampson and A. J. Stoeck, J. Am. Chem. Soc. 60, 1814 (1938). The model of the P₂O₅ molecule was later confirmed by the x-ray method reported by H. C. J. Decker and C. H. MacGillivray, Rec. trav. chim. 60, 153 (1941); and spectroscopic studies reported by H. Gerding and K. C. J. Decker, Rec. trav. chim. 65, 191 (1945), and T. A. Sidorov and N. N. Sobolev, Opt. Spectr. (USSR) 2, 717 (1957). All vibrational frequencies were obtained from E. P. Egan, Jr., private communication, Feb. 23, 1960, except nine frequencies, i.e. 170 (3), 470 (3) and 750 (3) cm⁻¹ which were estimated in order to make the second and third law values of ΔH_f^0 298.15 agree. The three principal moments of inertia are: $I_A = I_B = I_C = 1.4322 \times 10^{-37} \text{ cm}^2$. The heat capacities (549-1098°C. or 822-1371°K.) of P₂O₅ (g) have been determined by M. Prandsen, J. Res. Natl. Bur. Std. 10, 35 (1933). His results are in fair agreement with the calculated ones.

Bond Distance: W-O = [1.81] Å

Bond Angle: O-W-O = [109.47°], W-O₂-bridge-W = [160.53°]Product of the Moments of Inertia: $I_A I_B I_C = [3.854 \times 10^{-109}]$ g²cm⁶ $\sigma^\circ = [8]$

Heat of Formation

The adopted value, $\Delta H_f^{298}(\text{WO}_3, \text{g}) = -670.2$ kcal/mol, was reduced from $\Delta H_f^{1450}(\text{WO}_3, \text{g}) = -655.6$ kcal/mol of R. J. Ackermann and E. G. Rauh, J. Phys. Chem. **67**, 2598 (1963), who studied the sublimation behavior of the tungsten-oxygen system over the temperature range from 1300 to 1600°K by mass spectrometry, mass effusion and x-ray diffraction, and determined $\Delta H_f^\circ(\text{WO}_3, \text{g}) = -655.600 \pm 160.29$ T (cal/mol) from partial pressure measurements over the W-WO₃(c). They reviewed the previous determinations 1,2,3,4 of the thermodynamic properties of sublimation of WO₃, and also pointed out that it was not possible to make quantitative observations on stoichiometric WO₃ in vacuo, since it is a "bivariant" system and the ion current is not constant until the composition of the sample reaches WO_{2.98}. This is probably the cause of previous discrepancies in sublimation studies.

J. E. Battles, Ph. D. dissertation, "A Mass Spectrometric Investigation of Tungsten Dioxide and Tungsten Trioxide", The Ohio State University, 1964, has also studied the partial pressure of WO₃(g) over W-WO₃(c) in the temperature range from 1449 to 1527°K. Third law calculation of the partial pressure data gives $\Delta H_f^{298} = -172.0$ kcal/mol for $6 \text{ WO}_2(\text{c}) = \text{W}_6\text{O}_{12}(\text{g}) + 2 \text{ W}(\text{c})$, which yields $\Delta H_f^{298}(\text{WO}_3, \text{g}) = -675.6$ kcal/mol, using all JANAF functions.

Investigator	Chemical Reaction	Temperature (°K)	ΔH_f^{298} (kcal/mol)	Drift (eu)	$\Delta H_f^{298}(\text{WO}_3, \text{g})^\circ$ (kcal/mol)
Ackermann & Rauh	$6 \text{ WO}_2(\text{c}) = \text{W}_6\text{O}_{12}(\text{g}) + 2 \text{ W}(\text{c})$	1300 - 1600°	175.41	175.55	-670.2
Battles	$6 \text{ WO}_2(\text{c}) = \text{W}_6\text{O}_{12}(\text{g}) + 2 \text{ W}(\text{c})$	1449 - 1527°	176.16	172.01	-673.6

* Third law value adopted in calculation.

Heat Capacity and Entropy

The heat capacity was approximated by making a tentative choice of the vibrational frequencies of 800 cm^{-1} (s), 300 cm^{-1} (s), 240 cm^{-1} (s), and 200 cm^{-1} (s) in order to give the entropy at 1450°K , $S_{1450}^\circ = 276.9$ eu, corresponding to $\Delta H_f^{1450} = -160.29$ eu, reported by Ackermann and Rauh. The adopted value, $S_{298}^\circ(\text{WO}_3, \text{g}) = 144.6$ eu, was reduced from the entropy at 1450°K , using JANAF functions. Second law calculation of the partial pressure data of Battles gives $\Delta H_f^{1487} = 82.3$ eu for $6 \text{ WO}_2(\text{c}) = \text{W}_6\text{O}_{12}(\text{g}) + 2 \text{ W}(\text{c})$. This yields $S_{298}^\circ(\text{WO}_3, \text{g}) = 147.4$ eu.

The molecular configuration for $\text{W}_6\text{O}_{12}(\text{g})$ is estimated by assuming that the oxygens are tetrahedrally located around the tungsten atoms, and that each tetrahedron shares two oxygen atoms to form a planar eight-member ring. The bond distance W-O is estimated as 1.81 Å and the bond angles O-W-O = 109.47° and W-O₂-bridge-W = 160.53° . The three principal moments of inertia are $I_A = I_B = 5.855 \times 10^{-37}$ g cm², and $I_C = 1.034 \times 10^{-36}$ g cm².

Heat of Formation

Zero by definition below 704°K. See P₂(g) sheet for details above 704°K.

Heat Capacity and Extrapolation

The only reliable low temperature measurements, 15 to 305°K, are reported by R. L. Potter, Dissertation, Massachusetts Institute of Technology (1946). A value at 10°K was obtained by graphical extrapolation and a T³ function was assumed from 0 to 10°K. High temperature heat capacities were obtained from a smooth curve joining the measurements of O. Kubaschewski and O. Schrag, Z. Elektrochem. 46, 875 (1940), in the range 573 to 773°K and that of V. Regnault, Ann. chim. phys. 9, 322 (1843) at 331°K with those of Potter. Measurements of A. Wigand, Ann. Physik, 22, 64 (1907), are too high. The uncertainty in the high temperature heat capacity is about 2%.

Melting

The values of ΔH_m and T_m were calculated from the functions of the solid and liquid. This may be compared with a reported triple point of 862.7°K by A. Smits and S. C. Bokhorst, Verh. Akad. Wetenschap. 23, 930 (1914).

Heat of Sublimation

Vapor pressure measurements on the triclinic allotrope, T. V. A. designation V, are reported by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950). These data lead to a sublimation point of 704°K and ΔH_g° 298.15 of 30.77 ± 0.4 kcal. mole⁻¹ of P₄. A. Smits and S. C. Bokhorst, Z. phys. Chem. 91, 248 (1916), measured the vapor pressure of a sample whose preparation indicates that it was probably P, V. These results lead to ΔH_g° 298.15 = 30.6 ± 1 kcal. An unpublished value of 30.84 kcal. mole⁻¹ of P₄ by C. C. Stephenson is quoted by J. S. Kane, Thesis Univ. of California (1955).

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), show that the vapor density measurements of A. Stock, G. E. Gibson and E. Stamm, Ber. 45, 3527 (1912) are best explained by a vapor essentially composed of only P₄(g) below 800°K. This conclusion is supported by recent mass spectrometer measurements of J. S. Kane and J. H. Reynolds, J. Chem. Phys. 25, 342 (1956).

PHOSPHORUS, WHITE (P)

(CRYSTAL)

AT. WT. = 30.975

$$\Delta H_f^\circ = 3.75 \pm 0.2 \text{ kcal. mole}^{-1}$$

$$\Delta H_g^\circ = 3.52 \pm 0.05 \text{ kcal. mole}^{-1}$$

$$\Delta H_t^\circ = 124.62 \pm 0.2 \text{ cal. mole}^{-1}$$

$$\Delta H_m^\circ = 157.43 \pm 0.5 \text{ cal. mole}^{-1}$$

Heat Capacity and Extrapolation

Low temperature measurements, 15-315°K, were made by R. T. Maples, Dissertation, Massachusetts Institute of Technology (1949). A Debye θ temperature of 124 was used to extrapolate to 0°K. P. E. Young and J. H. Hildenbrand, *J. Am. Chem. Soc.* **54**, 859 (1942), obtained heat capacities from enthalpy measurements that are 4% higher than those from the low temperature calorimeter which are preferred because of the proximity to the melting point.

Transition

Observed by Maples.

Melting

The selected heat of fusion is that observed by Maples. Young and Hildenbrand obtain 125 cal. mole⁻¹ for the same quantity. Maples' value is consistent with vapor pressures and other thermochemical data; see P(11q) and P₄(g) sheets.

Heat of Sublimation

The vapor pressure measurements of P. S. Dainton and H. M. Kimberly, *Trans. Faraday Soc.* **46**, 912 (1950), are the most precise and lead to $\Delta H_{g,298.15}^\circ = 14.08 \pm 0.2 \text{ kcal. mole}^{-1}$ of P₄. Measurements of A. Jolibois, *Compt. rend.* **249**, 287 (1908), A. Smits and S. C. Bokhorst, *Z. Phys. Chem.* **91**, 246 (1916), and M. Gentszner, *Z. phys. Chem.* **95**, 89 (1913) lead to values that agree within the assigned uncertainty.

Heat of Formation

The heat of formation is obtained from the heats of sublimation represented by reaction I and II at 298.15°K.

See P, V sheet for details.

Of the calorimetric determinations only those of H. Giren, *Ann. Chim. Phys.* **30**, 203 (1903) result in a reliable value for the heat of formation, $4.4 \pm 0.4 \text{ kcal. mole}^{-1}$. A comprehensive review is given by H. J. Rodewald, *Helv. Chim. Acta* **43**, 878 (1960).

PHOSPHORUS (P)

(LIQUID)

AT. WT. = 30.975

$$\Delta H_{f, 298.15}^{\circ} = 5.2 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$\Delta H_{f, 298.15}^{\circ} = 10.25 \pm 0.03 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^{\circ}, P_A \rightarrow P(lq) = 157.43 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_m^{\circ}, P_V \rightarrow P(lq) = 4.5 \pm 0.2 \text{ kcal. mole}^{-1}$$

$$\Delta H_{f, 298.15}^{\circ} = 3.37 \pm 0.03 \text{ kcal. mole}^{-1}$$

$$P_c = [95.3] \text{ atm.}$$

Heat of Formation

Derived from the ΔH_m° by the following cycle:

$$(I) \quad P \quad 317.30 = P(lq) \quad 0.157 \text{ kcal.}$$

$$(II) \quad P_A \quad 298.15 = P_A \quad 317.30 \quad 0.113$$

$$(III) \quad P(lq) \quad 317.30 = P(lq) \quad 298.15 \quad -0.121$$

$$(IV) \quad P_V \quad 298.15 = P_A \quad 298.15 \quad 4.08$$

The $\Delta H_{f, 298.15}^{\circ}$ obtained from vapor pressure measurements on P_V and on the liquid is 4.32 kcal. mole⁻¹ in agreement with that derived from the melting point.

Heat Capacity

P. E. Young and J. H. Hildenbrand, J. Am. Chem. Soc. **64**, 839 (1942), obtained an equation from enthalpy measurements which decreased with temperature. However, a better fit to the thermochemical data results if a constant heat capacity is assumed.

Entropy

Derived from low temperature measurements on P_V , White. See P, White sheet for details.

Vaporization Phenomena

D. MacRae and C. C. Van Voorhis, J. Am. Chem. Soc. **43**, 547 (1921), determinations of the vapor pressure, 44 to 150°C, are the most precise and lead to a $\Delta H_{f, 298.15}^{\circ}$ of 13.504 ± 0.1 kcal. mole⁻¹ of P_4 . A vapor pressure equation derived by T. D. Farr, Tennessee Valley Authority Chemical Engineering Report No. 8 (1950) to fit the measurements reported in the literature leads to a value of 13.6 ± 0.1 kcal. mole⁻¹ of P_4 . The boiling point is calculated from the functions of $P(lq)$ and $P_A(g)$, and may be compared with the values of 552.7 and 553.7 resulting from Farr's equation and observations of A. Smits and S. C. Bokhorst, Proc. Akad. Wetenschap. **16**, 106 (1915) respectively.

Critical Phenomena

T_c determined and P_c estimated by W. Marchwald and R. Helmholz, Z. anorg. Chem. **124**, 81 (1922).

Heat of Formation.

The ΔH_f^o 298.15 was derived by the following cycle:

- (1) $4 P_{red}(v)$ [298.15°] = $P_4(g)$ [298.15°] $\Delta H_f^o = 30.77$ kcal. mole⁻¹ of P_4 See $P_{red}(v)$ sheet under Heat of Sublimation.
- (2) $P_4(g)$ [298.15°] = $2P_2(g)$ [298.15°] $\Delta H_f^o = 54.59$ kcal. mole⁻¹ of P_4 See $P_2(g)$ sheet under Heat of Formation.
- (3) $2P_2(g)$ [298.15°] = $2P_2(g)$ [0°] $\Delta H_f^o = 2(-2.128)$ kcal. mole⁻¹ of P_4 See $P_2(g)$ table.
- (4) $2P_2(g)$ [0°] = $4P(g)$ [0°] $\Delta H_f^o = 2(116.075)$ kcal. mole⁻¹ of P_4 A. G. Daydon, "Dissociation Energies and Spectra of Diatomic Molecules," Chapman and Hall, 1953.
- (5) $4 P(g)$ [0°] = $4 P(g)$ [298.15°] $\Delta H_f^o = 4(1.481)$ kcal. mole⁻¹ of P_4 See $P(g)$ table.

D_0^o for reaction (4) was given by A. G. Daydon (loc. cit.). He reported a predissociation limit at 51,958 ± 9 cm.⁻¹. He considered the dissociation to be $P_2 \rightarrow P(^4S) + P(^2D)$. From the predissociation limit and the energy level of the excited $P(^2D)$ state [11,360.8 cm.⁻¹] Daydon (loc. cit.) obtained a $D_0^o = 5.033$ e.v. or 116.075 kcal. mole⁻¹. As a check, a graphical Birge-Sponer extrapolation by Daydon (loc. cit.) [$\sum_{j=1}^{\infty} (v_j - v_0)$] agrees with a $D_0^o = 5.0$ e.v.

The vapor equilibrium data of G. Freuner and I. Brockmoller, Z. physik. Chem. **81**, 129 (1913) gave a ΔH_f^o for reaction (4) which was much lower than the spectroscopic value i.e. 31.5(1073°K) vs. 116(0°) kcal. mole⁻¹ of P_2 . D. P. Stevenson and D. M. Yost, J. Chem. Phys. **9**, 403 (1941) reported that the vapor equilibrium measurements of G. Freuner and I. Brockmoller (loc. cit.) were doubtful while the measurements of A. Stook, G. E. Gibson, and E. Stamm Ber **45**, 3527 (1913) were correct. Stook et al. (loc. cit.) have shown that the reaction $P_2(g) \rightarrow 2P(g)$ is extremely slight even at 1473°K which is the highest temperature of the vapor equilibrium studies.

Heat Capacity and Entropy.

The thermodynamic functions were calculated from the electronic levels which were evaluated by averaging the spectroscopic values of W. C. Martin, J. Opt. Soc. Am. **49**, 1071, (1959).

MONOPHOSPHORUS MONOSULFIDE (PS)

(IDEAL GAS)

GFW = 63.0378

Ground State Configuration $2^1\Pi$

$S^0_{298.15} = 56 \pm 0.2$ gibbs/mol

$\Delta H^0_{298.15} = 36.9 \pm 10$ kcal/mol

$\Delta H^0_{298.15} = 37.3 \pm 10$ kcal/mol

Electronic Levels and Quantum Weights

e_i , cm ⁻¹	g_i	g_i
0	0	2
324	324	2
[20000]	2	2
22000	4	4
34594	2	2

$\omega_e = 743.5 \pm 3.8$ cm⁻¹ $\omega_e X_e = 3.8 \pm 0.9$ cm⁻¹ $\sigma = 1$

$B_e = [0.29]$ cm⁻¹ $\alpha_e = [0.0016]$ cm⁻¹ $r_e = [1.92]$ Å

Heat of Formation

The dissociation energy (D^0_0) of PS(g) is estimated to be 140 ± 25 kcal/mol by comparison with the corresponding quantity for PO(g) and from a linear Birge-Sponer extrapolation of the third excited ($C^2\Sigma$) electronic state potential function. It is assumed that the $C^2\Sigma$ state dissociates to S(g) in its ground (3P) state and P(g) in its first excited (3D) state. The fundamental vibrational frequency in the $C^2\Sigma$ state (ω_e) is 531.8 ± 2.5 cm⁻¹ and the corresponding anharmonic term ($\omega_e X_e$) is 2.6 ± 0.5 cm⁻¹. These constants are calculated from a reanalysis of the spectral data of Dressler (1). The corresponding heat of formation of PS(g) is 37.3 ± 25 kcal/mol. The excited state ($C^2\Sigma$) data are used to calculate D^0_0 instead of the ground state(X¹ Π) data because the vibrational constants of the upper level are known more accurately and because the extrapolation is 50 kcal/mol smaller for this level.

Heat Capacity and Entropy

The spectra of PS(g) have been studied by Dressler (1) in the near UV and visible regions. He reported the above electronic levels which correspond to the doublet pi ground state and two of the excited levels ($B^2\Pi$, $C^2\Sigma$). The level of the first excited electronic state ($A^2\Sigma$) is estimated by analogy with NO(g).

Dressler (1) estimated the value of the rotational constant B_e . The value of α_e is calculated from the Morse potential function. The bond distance is calculated from B_e . The fundamental vibrational frequency ω_e and the anharmonic vibrational term $\omega_e X_e$ are calculated from a reanalysis of the spectral data reported by Dressler (1).

Heat of Formation

D. P. Stevenson and D. M. Yost, J. Chem. Phys. 9, 403 (1941), have shown that the vapor density measurements of A. Stock, O. E. Gibson and E. Stamm, Ber. 45, 3527 (1912), best fit a vapor composed of P₂ and P₄ molecular species. From these data T. D. Parr, Tennessee Valley Authority, Chemical Engineering Report No. 8, calculated the equilibrium constants which lead to a ΔH_f^o of P₂ for 1. From which ΔH_f^o of P₂ is obtained based upon a ΔH_f^o 298.15 of 30.77 kcal. mole⁻¹ of P₄(g).

(1) P₄(g) 298.15 = P₂(g) 298.15ΔH_r^o = 54.59 ± 0.1 kcal. mole⁻¹

Heat Capacity and Entropy

Molecular and spectroscopic constants are those listed by G. Herzberg, "Spectra of Diatomic Molecules", D. Van Nostrand Co. Inc., New York, 1945. More recent measurements of K. Dressler, Helv. Phys. Acta 28, 563 (1955) are in agreement with the values selected by Herzberg.

The dissociation energy is given by A. G. Gaydon, "Dissociation Energies", Chapman and Hall, Ltd., London, 1953.

PHOSPHORUS, TETRATOMIC (P₄) (IDEAL GAS)

MOL. WT. = 123.90

ΔH_f^o = 30.84 ± 0.5 kcal. mole⁻¹
 ΔH_f^o = 288.15 = 30.77 ± 0.5 kcal. mole⁻¹
 S_{298.15}^o = 66.89 ± 0.1 cal. deg.⁻¹ mole⁻¹

Point Group T_d

Vibrational Levels and Multiplicities

(ω, cm.⁻¹)

806 (1)
 363 (2)
 464.5 (3)

Bond Lengths and Angles P-P = 2.21 ± 0.2 Å
 Moments of Inertia I_A = I_B = I_C = 25.1 X 10⁻³⁹ g. cm.²
 P-P-P = 109°.28, ϕ = 12

Heat of Formation

Taken as the heat of sublimation of P (red, v).

Heat Capacity and Entropy

The frequency and multiplicities are those assigned by H. S. Gutowsky and G. S. Hoffman, J. Am. Chem. Soc. 72, 5751 (1950). Molecular parameters of the gas were determined from electron diffraction measurements by L. R. Maxwell, S. B. Hendricks and V. M. Moseley, J. Chem. Phys. 23, 699 (1955). C. D. Thomas and N. S. Gingrich, J. Chem. Phys. 23, 659 (1955) obtained a P-P distance of 2.25 Å from x-ray studies on the liquid. On the basis of the selected values for P, White (see sheet) a third law entropy of 66.89 cal. deg.⁻¹ mole⁻¹ is derived for P₄(g) at 298.15°K.

Tetraphosphorus Trisulfide (P_4S_3)
(Solid) Mol. Wt. = 220.098

TETRAPHOSPHORUS TRISULFIDE (P_4S_3) (solid)

Mol. Wt. = 220.098

$\Delta H_f^\circ 298.15 = [-37]$ kcal. mole⁻¹

$S_{298.15}^\circ = [48]$ cal. deg.⁻¹ mole⁻¹

$T_m = 440^\circ K.$

$\Delta H_m = [2.2]$ kcal. mole⁻¹

$\Delta H_f^\circ 298.15$ estimated from vapor density reported by D. M. Yost and H. Russell, "Systematic Inorganic Chemistry of the Fifth- and Sixth- Group Nonmetallic Elements", Prentice-Hall, New York (1944). T_m from Yost and Russell, loc. cit. Other data estimated.

$$\Delta H_{f0}^0 = 0$$

$$\Delta H_{f0}^0 \text{ 298.15} = 0$$

$$\Delta H_{f0}^0 \text{ 298.15} = 46.75 \pm 0.13 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 15.484 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_{f0}^0 = 1.141 \text{ kcal. mole}^{-1}$$

$$T_m = 800.58 \pm 0.00^\circ \text{K}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Heat capacity measurements have been reported by M. Horowitz, A. A. Silvini, S. P. Malaker and J. G. Daunt, (1° to 4°, 14° to 21°, and 64° to 77°K.), Phys. Rev. **88**, 1182 (1952); P. F. Meade, W. R. Forsythe and W. F. Giauque, (15° to 300°K.), J. Am. Chem. Soc. **55**, 1902 (1941); T. B. Douglas and J. L. Dever, (298.16° to 1200°K.), J. Am. Chem. Soc. **76**, 4824 (1954), and many others whose work is listed by K. K. Kelley, U. S. Bur. Mines Bull. 584 (1960).

Heat capacities from 15° to 300° and 1° to 4°K. (in superconducting state) were taken from Meade, Forsythe, and Giauque, and Horowitz, Silvini, Malaker, and Daunt, respectively. The missing data below the melting point were obtained by graphical extrapolation and joined smoothly to data of Douglas and Dever on approaching the melting point.

Melting.

The melting point of pure Pb(c) was found by E. H. McLaren and E. G. Mardock, Can. J. Phys. **38**, 577 (1960) to be $327.426 \pm 0.002^\circ \text{C}$. ΔH_m given by Douglas and Dever, loc. cit.

Heat of Sublimation.

ΔH_g^0 298.15 was derived from third law analysis of the vapor pressure data of W. H. Rodebush and A. L. Dixon, J. Am. Chem. Soc. **47**, 1038 (1925) and Phys. Rev. **26**, 851 (1925); A. C. G. Egerton, Proc. Roy. Soc. (London) **A103**, 469 (1923); P. Hartack, Z. physik. Chem. **134**, 1 (1928); A. T. Aldred and J. N. Pratt, Trans. Faraday Soc. **57**, 611 (1961); E. Baur and R. Brunner, Helv. Chim. Acta. **27**, 558 (1934), and J. Fischer, Z. anorg. Chem. **219**, 1, 367 (1934), which are in good agreement. Most weight was given to the results of Rodebush and Dixon. Older vapor pressure data of lower accuracy have not been used.

$$\Delta H_f^o 298.15 = [1.025] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^o = [17.141] \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$\Delta H_m^o = 1.141 \text{ kcal. mole}^{-1}$$

$$\Delta H_v^o = 42.53 \pm 0.13 \text{ kcal. mole}^{-1}$$

$$T_m = 600.58 \pm 0.00^\circ \text{K}$$

$$T_b = 2026^\circ \text{K}$$

Heat of Formation.

Obtained from ΔH_m^o .

Heat Capacity and Extrapolation.

Heat capacity from T_m to 1200°K taken from T. B. Douglas and J. I. Dever, J. Am. Chem. Soc. 76, 4824 (1954).
 C_p values below T_m and above 1200°K were extrapolated, a glass transition being assumed at 400°K.

Entropy.

Calculated from that of crystal.

Vaporization Phenomena.

 T_b and ΔH_v^o calculated from $\Delta H_f^o 298.15$ and functions for condensed and gaseous states.

From the vapor pressure, the free energy functions of Pb(g) and Pb₂(g), and the dissociation energy of Pb₂(g), it appears that below the boiling point the amount of Pb₂(g) in the vapor is negligible.

MOL. WT. = 414.42

(IDEAL GAS)

LEAD, DIATOMIC (Pb₂)

Ground State Configuration [5s²5p²]
 $\Delta H_f^\circ = 80.4 \pm 4.6 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ = 79.5 \pm 4.6 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$$\frac{\epsilon_i}{\epsilon_0} = \frac{g_i}{\sum g_i}$$

$$\omega_e x_e = 2.95 \text{ cm}^{-1}$$

$$\omega_e = [0.01727] \text{ cm}^{-1}$$

$$\sigma = 2$$

$$r_e = [3.08] \text{ \AA}$$

Heat of Formation.

$H_f^\circ = 256.5 \text{ cm}^{-1}$
 $B_e = [0.01727] \text{ cm}^{-1}$
 Heat of formation was calculated from the dissociation energy of Pb₂(g) reported by A. G. Daydon, "Dissociation Energies," Chapman and Hall Ltd., London, 1953.

Heat Capacity and Entropy.

The values of ω_e and $\omega_e x_e$ were obtained from G. Herzberg, "Spectra of Diatomic Molecules," D. Van Nostrand Company, Inc., New York, 1950. Those for B_e and ω_e were estimated according to the method suggested by G. Herzberg, loc. cit. The bond distance (r_e) was calculated from the moment of inertia, $I = 1630 \times 10^{-40} \text{ g. cm}^2$, estimated by K. K. Kelley and E. G. King, U. S. Bur. Mines Bull. 592, 1961. The ground state configuration was assumed to be 5s² by comparison to that for Si₂(g) reported by A. E. Douglas, Can. J. Phys. 33, 801 (1955).

Sulfur (S)

(Reference State) At. Wt. = 32.064

SULFUR (S)

SULFUR (S)

(CRYSTAL)

AT. WT. = 32.064

$$\Delta H_f^0 = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = 0 \text{ kcal. mole}^{-1}$$

$$\Delta H_f^0 = 96.01 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_f^0 = 0.38 \pm 0.2 \text{ cal. mole}^{-1}$$

$$\Delta H_f^0 = 410.52 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_f^0 \text{ 298.15} = 66.68 \pm 0.5 \text{ kcal. mole}^{-1}$$

$$S_{298.15}^0 = 7.63 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 368.5^\circ \text{K.}$$

$$T_{t_2} = 374^\circ \text{K.}$$

$$T_m = 368.5^\circ \text{K.}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

E. D. Eastman and W. C. McDoveck, J. Am. Chem. Soc. 59, 145 (1937), have measured the low temperature heat capacities of sulfur from 15° to 375°K. E. D. West, J. Am. Chem. Soc. 81, 29 (1959), has measured the high temperature heat capacities from 298° to 678°K. These two sets of data were joined smoothly at 298.15 K. by a graphical method.

The values of entropy at 110°C and above in E. D. West's paper (table VIII) have been lowered by 0.5841 joule. deg.⁻¹ mole⁻¹ because of a calculational error which was pointed out by J. P. McCullough and D. W. Scott, private communication, Sept. 27, 1960.

The entropy of rhombic sulfur at 298.15°K. was taken from E. D. Eastman and W. C. McDoveck, loc. cit., based on an extrapolation of $S_{15}^0 = 0.12 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Transition Data.

The enthalpies of transition at 368.5°K. and 374°K. were obtained from E. D. West, loc. cit. The first transition at 368.5°K. was the known rhombic-monoclinic transition, but the second one near 374°K. was a previously unreported transition.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Heat of Sublimation.

The heat of sublimation of sulfur (c) is the heat of formation of monatomic sulfur (g). See S(g) table for details. Since S_g and lower polymers are major vapor species at room temperature, the heat of sublimation to the equilibrium gas is much smaller. See $S_g(g)$ table for details.

Dec. 31, 1960; Dec. 31, 1965

$$\Delta H_f^{298.15} = 0.34 \pm 0.01 \text{ kcal. mole}^{-1}$$

$$\Delta H_m^{298.15} = 410.52 \pm 0.5 \text{ cal. mole}^{-1}$$

$$\Delta H_v^{298.15} = [2.30] \text{ kcal. mole}^{-1}$$

$$S_{298.15}^{298.15} = 8.44 \pm 0.5 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$$

$$T_m = 368.36^\circ \text{K.}$$

$$T_b = 717.75^\circ \text{K.}$$

Heat of Formation.

The $\Delta H_f^{298.15} (S, l)$ was obtained from that of the crystal by adding $\Delta H_m^{298.15}$ and the difference between $H_{298.15}^{298.15}$ for crystal and liquid.

Heat Capacity and Entropy.

The heat capacity of the liquid phase was obtained from E. D. West, J. Am. Chem. Soc. **81**, 29 (1959). No simple equation fits the curve of C_p against T which shows a peak.

The value of $S_{298.15}^{298.15} (S, l)$ was obtained in a manner analogous to that of the heat of formation. The heat capacity of sulfur (liquid) below the melting point was assumed to be constant as $7.579 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$, and above the boiling point, it was assumed as $7.694 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$.

Melting Data.

The heat of melting and the temperature were obtained from E. D. West, loc. cit.

Vaporization Data.

According to the international practical temperature scale, the boiling point is 717.75°K. The heat of vaporization to the equilibrium vapor mixture was estimated by D. R. Stull and G. C. Sink, "Thermodynamic Properties of the Elements," American Chemical Society, Washington, D.C., 1956. The equilibrium vapor involves monomeric and several polymeric species; S_2 and S_8 predominate above 1000°K. While S_8 , S_6 and possible S_4 and S_3 are favored at lower temperatures.

Heat of Formation.

L. Brewer, J. Chem. Phys. 21, 1143 (1953), has reviewed the three possible values of $D_0^\circ(S_2)$, i.e. 4.4 e.v., 3.6 e.v. and 3.3 e.v., which were due to the ambiguity of defining the excitation state of the atomic products resulting from predissociation in the spectroscopic measurements. The value of 4.4 e.v. (101.5 kcal. mole⁻¹) was shown to be the most probable one. Since this review, further support for his value have been given by the following investigators. J. R. Marquart, Dissertation Abstract 24, 5027 (1964), has found that the value of $D_0^\circ(S_2)$ to be consistent with the value of 4.4 e.v. in mass spectroscopic studies. R. Colin, P. Goldfinger and M. Jeunhomme, Trans. Faraday Soc. 60, 306 (1964), have found $D_0^\circ(S_2) = 97 \pm 5 \text{ kcal. mole}^{-1}$ in their mass-spectroscopic studies of the vaporization of CS_2 , CS_2 and CS_2 , but they reported a revised value, i.e. $D_0^\circ(S_2) = 101 \pm 1 \text{ kcal. mole}^{-1}$, which was given in the note in proof. A. N. Singh and D. K. Rai, J. Chem. Phys. 43, 2151 (1965), have selected the best value of $D_0^\circ(S_2) = 4.4 \text{ e.v.}$ in theoretical comparisons of the potential-energy curve. As pointed out by L. Brewer, loc. cit., and A. O. Gaydon, "Dissociation Energies", Chapman and Hall Ltd., 2nd. Ed., London, 1953, the old vapor pressure measurements which are not consistent with $D_0(S_2) = 4.4 \text{ e.v.}$ (101.5 kcal. mole⁻¹) are probably not reliable.

The value $D_0(S_2, g) = 4.4 \text{ e.v.}$ (101.5 kcal. mole⁻¹) was selected as the dissociation energy of diatomic sulfur, and combination of this value with heat of formation of diatomic sulfur gives the heat of formation of monatomic sulfur, $\Delta H_f^\circ 298(S, g) = 66.68 \text{ kcal. mole}^{-1}$.

Heat Capacity and Entropy.

The ground state configuration, electronic levels and quantum weight were obtained from C. E. Moore, "Atomic Energy Levels", Vol. 1, National Bureau of Standards Circular 467, June, 1949.

SULFUR, DIATOMIC (S_2)

(IDEAL GAS)

MOL. WT. = 64.128

Ground State Configuration $3\Sigma_g^-$
 $S_{298.15}^\circ = 54.51 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$

$\Delta H_f^\circ 0 = 30.80 \pm 0.2 \text{ kcal. mole}^{-1}$
 $\Delta H_f^\circ 298.15 = 30.84 \pm 0.2 \text{ kcal. mole}^{-1}$

Electronic Levels and Quantum Weight

$\epsilon, \text{ cm.}^{-1}$ g_i

0	3
---	---

$\omega_e = 724.68 \text{ cm.}^{-1}$
 $x_e = 2.852 \text{ cm.}^{-1}$
 $\alpha_e = 0.0018 \text{ cm.}^{-1}$

$\sigma^+ = 2$
 $r_e = 1.889 \text{ \AA}$

Heat of Formation.

The standard enthalpy of formation of gaseous diatomic sulfur, $\Delta H_f^\circ 298 = 30.84 \text{ kcal. mole}^{-1}$, was calculated from $\Delta H_f^\circ 298 = -20.30 \text{ kcal. mole}^{-1}$ for the reaction $H_2(g) + 0.5 S_2(g) \rightarrow H_2S(g)$ with JANAP value $\Delta H_f^\circ 298(H_2S, g) = -4.88 \pm 0.15 \text{ kcal. mole}^{-1}$. The $\Delta H_f^\circ 298$ was obtained by the second and third law analyses of equilibrium constants which have been determined by G. Freuner and W. Schupp (ref. 1) and M. Randall and P. R. Bichowsky (ref. 2). The results obtained are presented as follows:

Ref.	Temp. Range	Points	2nd law $\Delta H_f^\circ 298 \text{ kcal. mole}^{-1}$	3rd law $\Delta H_f^\circ 298 \text{ kcal. mole}^{-1}$	Drift cal. mole ⁻¹ deg. ⁻¹
1	1023-1405°K	5	-19.92 ± 0.13	-20.295	-0.282 ± 0.097
2	1362-1667°K	4	-20.74 ± 0.40	-20.307	$+0.281 \pm 0.269$
3	1023-1667°K	9	-20.13 ± 0.12	-20.300	-0.066 ± 0.083

References

3. Combination of above references.

The third law value of the combination set was selected to calculate the heat of formation of diatomic sulfur.

The dissociation energy of gaseous diatomic sulfur, $D_0^\circ(S_2) = 101.5 \text{ kcal. mole}^{-1}$, was chosen. For discussions see JANAP monatomic sulfur (g) and sulfur monoxide (g) tables.

Heat Capacity and Entropy.

The molecular constants which were taken from G. Herzberg, "Spectra of Diatomic Molecules", 2nd Ed., D. Van Nostrand Company, New York, have been modified for the natural isotopic abundances reported by D. Strominger, J. M. Hollander and G. T. Seaborg, Rev. Mod. Phys. **30**, 585 (1958).

December 31, 1960.

Silicon Disulfide (SiS₂) (Crystal)

Mol. Wt. = 92.222
ΔH_f^o 298.15 = -50.7 kcal. mole⁻¹
S_{298.15} = [16.0] cal. deg.⁻¹ mole⁻¹
T_m = 1363°K.
ΔH_m = [5.0] kcal. mole⁻¹

Heat of Formation. ΔH_f^o 298.15 was calculated from the measured ΔH_f^os of the following reactions:

ΔH_{R1} was taken from R. Rocquet, M. T. Ancey-Maret, Bull. Soc. Chim. France 1954, 1059 (1954); ΔH_{R2} was from D. Torgeson and Th. G. Samaha, J. Am. Chem. Soc. 76, 2156 (1954). ΔH_f^o 298.15 of SiS₂ was recalculated using the corrected value for ΔH_f^o 298.15 of SiO₂.

Heat Capacity and Entropy. C_p and S_{298.15} values are estimated.

Melting Data. T_m was from National Bureau of Standards Circular 500, "Selected Values of Chemical Thermodynamic Properties", 1952. ΔH_m was estimated.

σ = 8

Heat of Formation.

The vapor pressure of S(g) has been measured by many investigators. Using the seven more recent vapor pressure data, the respective heat of sublimation (ΔH_g^{298.15}) was calculated by both the third and second law methods. The values obtained are tabulated as follows:

Investigator	Temperature Range, °K.	ΔH _g ^{298.15} , kcal. mole ⁻¹
West-Menzies ¹	376.6 - 446.8	24.29
Neumann ²	352.6 - 362.1	24.35
Fourtner ³	304.1 - 351.6	24.36
Tallade ⁴	303.6 - 352.5	24.29
Bradley ⁵	288.3 - 305.7	24.29
Magee ⁶	331.9 - 368.0	24.11
Briske ⁷	332.7 - 367.4	23.88
	275.2 - 313.2	24.28
		24.00

¹ W. A. West and A. W. Menzies, J. Phys. Chem. **53**, 1880 (1959).² K. Neumann, Z. physik. Chem. **117**, 416 (1954).³ G. Fourtner, Compt. rend. **218**, 194 (1944).⁴ M. Tallade, Compt. rend. **218**, 836 (1944).⁵ R. S. Bradley, Proc. Roy. Soc. (London) **A 205**, 553 (1951).⁶ D. W. Magee, Ph. D. Thesis, The Ohio State University, 1955.⁷ C. Briske, N. H. Hartshorne and D. R. Stranks, J. Chem. Soc. (London), 1200 (1960).

Due to the presence of S₈(g) in S₈(g), the measured total pressures were corrected to give the partial pressures of S₈(g) for the first five sets of vapor pressure data, according to D. W. Scott, U. S. Bureau of Mines, Bartlesville, Oklahoma, private communication, May 22, 1964. However, the magnitude of the correction is only 0.1 - 0.2 kcal. mole⁻¹. The adopted value is the weighted average of both the third and second law values.

Heat Capacity and Entropy.

The vibrational frequencies were taken from D. W. Scott, J. P. McCullough and F. H. Krue, "Vibrational Assignment and Force Constants of S₈ (condensed States) from a Normal-Coordinate Treatment", Prepublication Report 64, U. S. Bureau of Mines, May 20, 1963. Four of the eighteen frequencies, i.e. 86(2) and 218(2) cm.⁻¹, were changed to 56(2) and 248(2) cm.⁻¹, respectively, suggested by D. W. Scott, loc. cit., private communication, April 23, 1964. The molecular structure and bond distance and angle were reported by J. Donohue, A. Caron and E. Goldstein, J. Am. Chem. Soc. **83**, 3748 (1961). The three principle moments of inertia are: I_A = I_B = 1.28594 × 10⁻⁵⁷ and I_C = 2.36042 × 10⁻⁵⁷ g. cm.².

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Low temperature heat capacities are based on the precise data (8-300°K) of Flubacher, Leadbetter and Morrison. The entropy is obtained from the heat capacity using $S_g^\circ = 0.0003$ eu. The selected values are consistent with recent data of Keesom and Seidel (1.2 - 4.2°K) and Kailishevich et al. (60-300°K). Earlier data have been reviewed by R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965.

High temperature studies are summarized below, along with the pertinent low temperature studies. The selected heat capacities above 300°K are obtained from a Shomate plot of the adopted low temperature heat capacities and the enthalpies reported or derived from the work of Dennison (1963), Kantor et al. (1960), Olette (1956), Serebrennikov and Gel'd (1952), and Magnus (1952). Discrepancies are apparent in the enthalpy data, particularly in the range of 370 to 1100°K, where only the recent study of Dennison made use of a high purity sample. Enthalpies from Dennison join most smoothly with the low temperature C_p° but deviate increasingly at higher temperatures, being 1-2% lower than the other measurements above 1000°K. The selected functions agree with Dennison below 600°K, with Magnus from 600 to 1200°K, and with Kantor et al. above 1200°K. The resulting heat capacities are slightly different from those selected by Hultgren et al., loc. cit.; the latter are 0.07 gibbs/mol higher at 800°K and 0.21 gibbs/mol lower at the melting point.

Investigators	Method	Quantity Reported	T Range, °K	Sample
1. Flubacher et al. (1959)	Calorimetry	C_p°	7.7 - 300	Single crystal, annealed, resistance (300°K) 0.027 ohm cm, Carrier Concentration $\leq 10^{15} \text{ cm}^{-3}$
2. Keesom et al. (1959)	Calorimetry	Specific Heat	1.2 - 4.2	
3. Kailishevich et al. (1965)	Calorimetry	C_p°	60 - 300	99.99%
4. Gerlich et al. (1965)	Temperature Modulation	C_p°	300 - 900	Resistance (300°K) = 0.027 ohm cm, Carrier Concentration = 10^{19} cm^{-3}
5. Dennison (1963)	Drop Calorimetry	Specific Heat	273 - 1373	Resistance (300°K) = 107 ohm cm
6. Kantor et al. (1960)	Drop Calorimetry	Enthalpy Equation	1148 - 1695	"Highly purified"
7. Olette (1956)	Drop Calorimetry	Specific Enthalpy	1467 - 1695	99.99%
8. Serebrennikov et al.	Drop Calorimetry	Specific Enthalpy	302 - 1556	99.3%
9. Magnus (1952)	Drop Calorimetry	Specific Enthalpy	372 - 1175	99.2%

SILICON (Si) (LIQUID) GFW = 28.086

$S_{298.15}^{\circ} = 10.426$ gibbs/mol
 $\Delta H_f^{\circ} = 11.585$ kcal/mol
 $\Delta H_m^{\circ} = 12.0 \pm 0.1$ kcal/mol
 $\Delta H_v^{\circ} = [92.047]$ kcal/mol
 $\Delta H_v^{\circ} = [85.8]$ kcal/mol

T_m = 1685 ± 3°K

T_b = [3513.8] °K (to monomer only)

T_b = [3492] °K (to equilibrium mixture)

Heat of Formation.

The heat of formation is obtained from that of the crystal by adding ΔH_m° and the difference between $H_{298.15}^{\circ}$ - $H_{298.15}^{\circ}$ for crystal and liquid.

Heat Capacity and Entropy.

Enthalpy data for high purity samples in quartz or vitreous silica capsules have been reported for the range 1698-1915°K by P. B. Kantor, A. M. Kisil and E. M. Fomichev, Ukrain. Fiz. Zhur. 5, 358 (1960), and for the range 1686-1825°K by M. Olette, Phys. Chem. Steelmaking, Proc. Dedham, Mass. 1955, 18-28 (Pub. 1958). Due to the limited temperature range and the experimental uncertainty, the data do not appear to justify more than a constant heat capacity. A value of 6.5 gibbs/mol is selected, intermediate between the values of 6.75 and 6.15 obtained from the separate experiments. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data.

Modern determinations of the melting point range from 1683 ± 1 to 1690 ± 4°K, the former from the specific volume study of L. D. Lucas and G. Urbain, Compt. Rend. 255, 2414 (1962), and the latter from the enthalpy study of Kantor et al. The selected value of T_m = 1685°K is taken from R. Hultgren, R. L. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965, who have reviewed the melting data. The heat of melting is calculated from the selected enthalpy of the crystal and the liquid enthalpy measurements of Kantor et al. and Olette, who reported comparable values of $\Delta H_m^{\circ} = 11.95 \pm 0.18$ and 12.085 ± 0.1 kcal/mol, respectively.

Vaporization Data.

T_b is calculated as the temperature for which the $\Delta G_r^{\circ} = 0$ for Si(l) = Si(g). ΔH_v° is calculated as the difference between $\Delta H_f^{\circ}(g)$ and $\Delta H_f^{\circ}(l)$ at T_b. The normal boiling for the equilibrium vapor is calculated as the temperature at which Si₁, Si₂ and Si₃ attain a total pressure of one atm. ΔH_v° at this temperature is calculated as the enthalpy of vaporization of one GFW of liquid to vapor containing 92.1, 7.0 and 0.9 mole percent of monomer, dimer and trimer, respectively. Tetramer and higher polymers, which are ignored in the equilibrium calculation, are probably negligible at this temperature.

Heat of Formation

The heat of formation is the heat of sublimation, $\Delta H_{298.15}^\circ = 107.7$ kcal/mol, selected from third law analyses of the vapor pressure data reviewed below. Langmuir, Knudsen and transport studies are all in satisfactory agreement throughout the range of 1400 - 2000°K. In addition, O. C. Trueman and P. O. Schlassel, Condensation Evaporation Solids Proc. Symp., Dayton, Ohio 1962, 313-17 (Pub. 1964), have experimentally verified that the vaporization coefficient is about 0.8 at 1300°K. This was accomplished by mass spectrometric determination of the Langmuir and Knudsen rates of sublimation from a single crystal sample in a cell designed to give Knudsen effusion from one end and free evaporation from the other end.

The recent studies confirm the mass spectrometric data of R. E. Honig, J. Chem. Phys. 22, 1610 (1954), and substantiate the author's postulate that vapor pressures obtained in early boiling point experiments are too large due to reaction or decomposition of the alumina and silicon carbide containers. In their review of the earlier experiments, R. Hultgren, R. I. Orr and K. K. Kelley, "Supplement to Selected Values of Thermodynamic Properties of Metals and Alloys," Univ. of California, Berkeley, November, 1965, calculated apparent heats of sublimation of less than 90 kcal/mol from the data. Neither these values nor the value of 92 kcal/mol, obtained from the Knudsen data (1485 - 1593°K) of A. V. Tselyayeva, Yu. A. Priselkov and V. V. Karelin, Vestnik Moskov. Univ., Ser. 2 Khim. 15, No. 5, 36 (1960), were considered in the JANAF selection. It is not clear why Tselyayeva et al. obtain pressures larger by a factor of 200 from their molybdenum cell.

Heat Capacity and Entropy

Electronic levels and quantum weights are from L. J. Radziemski and K. L. Andrew, J. Opt. Soc. Am. 55, 474 (1965), and V. Kaufman, L. J. Radziemski and K. L. Andrew, ibid. 55, 911 (1966). An additional level with quantum weight of 200 is estimated above the observed levels and below the dissociation limit; however, the effect of this level on the entropy at 6000°K is negligible. Levels above 39000 cm^{-1} are averaged.

$\sigma = [2]$

Heat of Formation.

The selected value is an average based on the equilibrium data summarized below. Drowart and co-workers have used the Knudsen effusion-mass spectrometric technique to determine the vapor species over the systems SiC-graphite¹ and SiC-silicon². Third law analysis of the partial pressures of Si₃ and Si yields the values 154.0 and 149.9 kcal/mol. Both drifts suggest that the entropy may be lower than the tabulated values. It is unlikely that the entropy is in error by more than 5 eu so that most of the drift is inherent in the data. The adopted value of $\Delta H_f^\circ = 152 \pm 10$ kcal/mol includes allowance for an error of up to 5 eu.

*For reaction $\text{Si}_3(\text{g}) = 3 \text{ Si}(\text{g})$

Heat Capacity and Entropy.

Wetmore and McLeod³ observed an absorption band near 4660 Å in matrix isolation studies. Their tentative assignment of this band as the $\Sigma_u^- \leftarrow \Sigma_g^-$ transition of Si₃ is adopted here. A $1W_u$ state is assumed at 18000 cm⁻¹, which is 7000 and 2000 cm⁻¹ below the analogous levels³ for C₃ and C₂Si. Also a $3W_u$ level is assumed at 10000 cm⁻¹, presumably arising from the same molecular orbital configuration as the $1W_u$ state. The molecule is assumed to be linear with a bond distance equal to that in Si₂. Vibrational frequencies are estimated from a valence bond calculation using $k_1 = 2.16 \times 10^5$ and $k_2/k_1 = 0.11 \times 10^5 \text{ dyn/cm}$. The stretching force constant is obtained from Si₂, while the bending force constant is based on C₂Si and the $1W_u$ excited state³ of C₃. The moment of inertia is $47.22 \times 10^{-39} \text{ g cm}^2$.

$\Delta H^\circ_{298.15} = 7.325 \pm 0.02$ gibbs/mol
 $\Delta H^\circ_{298.15} = 0$ kcal/mol
 $\Delta H^\circ = 0.99$ kcal/mol
 $\Delta H^\circ_{298.15} = 113.0 \pm 1.0$ kcal/mol

Heat of Formation.
Zero by definition.
Heat Capacity and Entropy.

The low temperature heat capacities, 1.1 - 305.51°K, have been measured by many investigators. Their measured temperature range, specimen purity and value of $S^\circ_{298.15}$ reported are listed in the following table. The Cp values, below 298°K, adopted were mainly derived from the data obtained from references 3, 5 and 6, which are in good agreement with other sets of Cp data.

Investigator	Temperature, °K	Purity, %	$S^\circ_{298.15}$, eu
1. K. K. Kelley (1944)	53.5 - 295.1	98.75	7.24 ± 0.07
2. Estermann et al. (1952)	1.8 - 4.2	99	-
3. Kothen and Johnston (1953)	15.44 - 305.51	99.98	7.33 ± 0.02
4. Aven et al. (1956)	3.95 - 15.78	99.95	-
5. Wolcott (1957)	1.17 - 20.95	99.98	-
6. Clusius and Franzosini (1958)	13.72 - 271.92	99.98	-
7. Burk et al. (1958)	22.5 - 200.0	99	-
8. Kneip et al. (1963)	1.1 - 4.5	99.66	-
9. Hake and Cape (1964)	1.2 - 4.5	99.92	-
1. K. K. Kelley, Ind. Eng. Chem. 36, 865 (1944). $S^\circ_{50.12} = 0.401$ eu.			
2. I. Estermann, S. A. Friedberg and J. E. Goldman, Phys. Rev. 87, 582 (1952).			
3. C. W. Kothen and H. L. Johnston, J. Am. Chem. Soc. 75, 3101 (1953). $S^\circ_{15} = 0.013$ eu.			
4. M. H. Aven, R. S. Craig, T. R. Waite and W. E. Wallace, Phys. Rev. 102, 1263 (1956).			
5. N. M. Wolcott, Phil. Mag. 2, 1246 (1957).			
6. K. Clusius and P. Franzosini, Z. Physik. Chem. 16, 194 (1958).			
7. D. L. Burk, I. Estermann and S. A. Friedberg, Z. Physik. Chem. 16, 183 (1958).			
8. O. D. Kneip, Jr., J. O. Betterton, Jr. and J. O. Scarbrough, Phys. Rev. 130, 1687 (1963).			
9. R. P. Hake and J. A. Cape, Phys. Rev. 135, A1151 (1964).			

The high temperature heat capacities, 320-1856°K, have also been determined by many investigators. The values above 1155°K are not in good agreement. The measured temperature range, method used, and kind of data reported by these investigators are presented in the table below.

Investigator	Temperature, °K	Method	Property Measured
1. Jaeger et al. (1936)	492.9 - 1475.6	drop calorimetry	$H^\circ_T - H^\circ_{298.15}$
2. Kothen (1952)	1067.0 - 1856.0	drop calorimetry	$H^\circ_T - H^\circ_{298.15}$
3. Scott (1957)	333.2 - 1233.2	adiabatic calorimetry	Cp
4. Backhurst (1958)	873.2 - 1353.2	adiabatic calorimetry	Cp
5. Golutvin (1959)	388.0 - 1401.9	drop calorimetry	$H^\circ_T - H^\circ_{298.15}$
6. Holland (1963)	595.0 - 1345.0	resistance measurement	Cp
7. Kohlhaas et al. (1965)	320.0 - 1800.0	adiabatic calorimetry	Cp
1. F. M. Jaeger, E. Rosenbohm and R. Fonteyne, Rec. trav. chim. 55, 615 (1936).			
2. C. W. Kothen, Ph. D. Dissertation, The Ohio State University, 1952. Sample purity 99.96%.			
3. J. L. Scott, ORNL-2328, Oak Ridge National Laboratory, July 1957.			
4. I. Backhurst, J. Iron Steel Inst. (London) 189, 124 (1958).			
5. Y. M. Golutvin, Russ. J. Phys. Chem. 33, 164 (1959).			
6. L. R. Holland, J. Appl. Phys. 34, 2350 (1963).			
7. R. Kohlhaas, M. Braun and O. Vollmer, Z. Naturforsch. 20a, 1077 (1965). Sample purity 99.96%.			

The adopted Cp values, 298.15 - 1155°K, were mainly derived from the Cp data reported by reference 7. The low temperature and high temperature Cp data were joined smoothly at 298°K. The Cp values above 1155°K were estimated by graphical extrapolation. $S^\circ_{298.15}$ was derived from the adopted Cp, based on $S^\circ_{13} = 0.015$ eu.

Transition Data.

See the Ti (β, c) table for details.

Heat of Sublimation.

 $\Delta H^\circ_{298.15}$ is calculated as the difference between $\Delta H^\circ_{298.15}$ for Ti(g) and Ti (α, c).

T, °K	Cp ^a	$\frac{\text{gibbs/mol}}{S^{\circ}} - (G^{\circ} - H^{\circ}_{298})/T$	$H^{\circ} - H^{\circ}_{298}$	$\frac{\text{kcal/mol}}{\Delta H^{\circ}}$	ΔG°	Log Kp

Sept. 30, 1956

ΔH°_0 = Unknown
 $\Delta H^{\circ}_{298.15} = 1.433$ kcal/mol
 $\Delta H^{\circ} = 0.99$ kcal/mol
 $\Delta H^{\circ} = [4.45]$ kcal/mol
 $\Delta H^{\circ}_{298.15} = [111.57]$ kcal/mol

Heat of Formation.

The heat of formation ($\Delta H^{\circ}_{298.15}$) was obtained from $\Delta H^{\circ}_{298.15}$ (α , c) by adding ΔH° and the difference $H^{\circ}_{Ti} - H^{\circ}_{298.15}$ for Ti (α , c) and Ti (β , c).

Heat Capacity and Entropy.

The heat capacities, 1155 - 1856°K, have been determined by many investigators. See the Ti (α , c) table for details. The selected Cp values were evaluated based on the data reported by C. W. Kothen, Ph. D. dissertation, The Ohio State University, 1952, and R. Kohlhaas, M. Braun and O. Vollmer, Z. Naturforsch. 20A, 1077 (1965). The heat capacities below 1155°K and above 1800°K were estimated by graphical extrapolation. The entropy was obtained in a manner analogous to that of the heat of formation.

Transition Data.

Titanium has two crystal forms, i.e., the hexagonal close-packed low-temperature form and the body-centered cubic high-temperature form. The $\alpha \rightarrow \beta$ transition temperature has been determined and reported over a range of temperatures, 1154-1167°K, by many investigators. The value of Tt is affected by the impurities in the specimen or adsorbed by the specimen during the measurement and the method used for the determination. The following table indicates the values of Tt reported by different investigators. Also included are the heats of transition (ΔH°_t), purity of specimen and property measured. The value of Tt adopted is 1155 \pm 3°K, and the value of ΔH°_t is selected as 0.99 kcal/mol.

Investigator	Tt, °K	ΔH°_t , kcal/mol	Purity, %	Method or Property Measured
1. Fast (1939)	1159 \pm 10	-	Iodide	electrical resistance
2. Greiner and Ellis (1949)	1158 \pm 2	-	99.9	electrical resistance
3. McQuillen (1950)	1155.7 \pm 1	-	99.93	hydrogen solubility
4. Dwez (1951)	1155 \pm 4	-	Iodide	cooling curve
5. Wornor (1951)	1158 \pm 2	-	99.93	thermoelectric power
6. Kothen (1952)	1154	0.943	99.96	dropping calorimetry
7. Edwards et al. (1953)	1157 \pm 3.5	-	99.88	cooling curve
8. Schofield (1956)	1158	0.814	-	rate of heating
9. Scott (1957)	1156 \pm 2	0.978 \pm 0.025	Iodide	adiabatic calorimetry

Melting Data.

See the Ti(l) table for details.

Heat of Sublimation.

$\Delta H^{\circ}_{298.15}$ is calculated as the difference between $\Delta H^{\circ}_{298.15}$ for Ti(g) and Ti (β , c).

Heat of Formation

The vapor pressure of Ti (β), 1510-1822°K, has been measured in three separate investigations. Based on the reported vapor pressures, the enthalpies of sublimation (ΔH_{sub}°) are evaluated by both the second and third law methods. The results obtained are presented in the following table. The adopted value of ΔH_f° for Ti(g) is 113.0 ± 1.0 kcal/mol.

Reference	Temperature, °K	ΔH_f° , kcal/mol	Drift, eu
1	1510 - 1822	Second Law Value	
2	1658 - 1808	112.23 \pm 1.91	110.26 \pm 0.81
3	1587 - 1764	112.41 \pm 6.30	110.71 \pm 1.10
		112.26 \pm 1.12	111.79 \pm 0.18
		112.26 \pm 0.18	111.79 \pm 0.18
		ΔH_f° (3rd law)	111.69
		ΔH_f° (2nd law)	113.22

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from C. E. Moore, National Bureau of Standards Circular 467 (1949). However, above the level $\epsilon_i = 15877.17$ cm⁻¹, the values of ϵ_i and g_i listed in the above table are average values calculated from those given by Moore. The $S^\circ_{298.15}$ level of the ground multiplet which has not been observed is estimated to lie at 12000 cm⁻¹ by comparison with the corresponding levels for Ti²⁺ ion, Zr and Zr²⁺ ion reported by C. E. Moore, loc. cit.

Heat of Formation

The heat of formation is calculated from the reaction $\text{Ti(g)} = \text{Ti}^+(\text{g}) + e^-(\text{g})$ with the JANAF auxiliary value for Ti(g) and an ionization potential = 6.82 eV or 157,276 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. III, 1958.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. I, 1949. The electronic levels above 4700 cm^{-1} are averaged. The $H^{\circ} - H^{\circ}_{298}$ value at 0°K is -1.888 kcal/mol.

 $\Delta H^\circ_{298,15} = 203.4 \pm 1.5 \text{ kcal/mol}$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

There have been several investigations of the low temperature heat capacity of tungsten: F. Lange, Z. Physik. Chem. **110**, 343 (1924), covered the range 28-91°K. M. Horowitz and J. G. Daunt, Phys. Rev. **91**, 1099 (1953), reported values in the range 1-77°K, while T. R. Waite, R. S. Craig, and W. E. Wallace, Phys. Rev. **104**, 1240 (1956), worked from 4-15° and W. DeSorbo, J. Phys. Chem. **62**, 965 (1958), from 15-90°K. C. Zwikker and G. Schmidt, Z. Physik. **52**, 668 (1928) covered the range from 90 to 2521°K. K. Clausius and P. Franzosini, Z. Naturforsch. **14a**, 99 (1959), made a thorough study of the heat capacity in the range 12-274°K, and their measurements were adopted leading to $S^\circ_{298} = 7.806$ eu based on $S^\circ_{12,5} = 0.0088$ eu. This value is in disagreement with the quoted value of 7.63 eu but agrees exactly with a separate integration by V. A. Kirillin, A. E. Sheindlin, V. Ya. Chekhovskoi and V. A. Petrov, Zhur. Fiz. Khim. **37**, 2249 (1963). In the intermediate temperature range the adiabatic heat capacity measurements of R. L. Bronson, H. M. Chisholm and S. M. Docketty, Can. J. Res. **B**, 282 (1953), from 253 to 773°K joined well with the low temperature measurements and were adopted. The high temperature enthalpies have been measured by several investigators from which were selected the values of P. M. Jaeger and E. Rosenblum, Rec. trav. chim. **51**, 1 (1932), from 273-1800°K; A. Magnus and H. Holzmann, Ann. Physik Ser. **5**, 585 (1929), who covered the range 373 to 1173°K; M. Hoch and H. L. Johnston, J. Phys. Chem. **65**, 855 (1961) who made measurements between 1382 and 2900°K; Kirillin et al., loc. cit., who have made several determinations over the range 600 to 3100°K, and have also analyzed the above data and have presented smooth functions from 0 to 3500°K. The present table agrees with that of Kirillin et al. up to 2700°K. Above this temperature the values of Cp adopted follow those reported by I. I. Novikov and P. G. Streikov, Vestnik. Akad. Nauk SSSR **34**, 26(1964), measured by an electric modulation method, up to the melting point. These values rise rapidly above 2700°K and are not inconsistent with the individual measurements of Kirillin et al. at their highest temperatures.

Melting Data.

I. Langmuir, Phys. Rev. **5**, 138 (1915), determined the melting point as 3540°K from intrinsic brilliance measurements; this was later corrected to 3655 ± 30°K by H. A. Jones, I. Langmuir and G. M. J. Mackay, Phys. Rev. **30**, 201 (1927). M. Firani and H. Alterthum, Z. Elektrochem. **29**, 5 (1923), from pyrometer measurements on a black body hole found 3660 ± 60°K. Using the same technique C. F. Zalabak, NASA Tech. Note D-761 (1961), reports 3680°K on a low carbon specimen; he reports a decrease of the melting point with increasing carbon content. E. Rudy and S. Windisch, Aerojet-General Tech. Rept. No. APWL-TR-65-2 Part 1, Vol. III July 1965, report a melting point of 3696 ± 20°K. The value adopted was 3680 ± 20°K. The heat of melting was obtained by assuming an entropy of melting of 2.3 eu obtained from a comparison of several high melting metals (Fe, Cu, Co, Mg, Al).

Sublimation Data.

See W(g) for details.

TUNGSTEN (W) (LIQUID)

OPW = 183.85

S_{298.15}^o = 10.923 gibbs/molΔH_{f298.15}^o = 11.223 kcal/molT_m^o = 3680 ± 20°KΔH_m^o = [8.46 ± 2.5] kcal/molT_b^o = [5936]°KΔH_v^o = [192.824] kcal/mol

Heat of Formation.

The heat of formation at 298°K was calculated from that of the crystal by adding ΔH_m^o and the difference between H₃₆₈₀^o - H₂₉₈^o for (c) and (l).

Heat Capacity and Entropy.

The heat capacity was estimated as 8.5 gibbs/g-atom by analogy with other monatomic metals. The entropy at 298°K was calculated in a manner analogous to that of the heat of formation. At 2500°K a glass transition was assumed, below which the heat capacity was that of the crystal.

Melting Data.

See crystal table for details.

Vaporization Data.

The boiling point and heat of vaporization were calculated from the adopted functions and heat of sublimation in order to maintain proper thermodynamic consistency.

Ground State Configuration $5d_0$

$\Delta H_f^\circ = 203.1 \pm 1.5$ kcal/mol

$\Delta H_f^{298.15} = 203.4 \pm 1.5$ kcal/mol

$S_{298.15}^\circ = 41.549$ gibbs/mol

Heat of Formation.

ΔH_f^{298} is the heat of sublimation of the crystal at 298°K; this has been obtained by 2nd and 3rd law analysis of the vapor pressure data of three investigators. The results are summarized below:

Ref.	Range*°K	Points	$\Delta H_f^{298.15}$ kcal/mol	3rd law drift eu
1	2511-3053	12*	200.9 \pm 3.6	0.1 \pm 1.4
2	2383-3123	14	214.8 \pm 1.4	202.17 \pm 2.5
3	2574-3183	10	202.4 \pm 2.7	203.35 \pm 1.2

*1 point rejected due to failure of a statistical test.

**All temperatures are taken from Ref. 3, in which the earlier measurements have been corrected.

References:

1. H. A. Jones, I. Langmuir and O. M. J. Mackay, Phys. Rev. **30**, 201 (1927).
2. C. Zwicker, Physica **5**, 249 (1925).
3. R. Szwarc, E. R. Plante, and J. J. Diamond, J. Res. Natl. Bur. Std. **69A**, 417 (1965).

The values are remarkably good, since even at the highest temperature the pressures are less than 10^{-6} atm; all workers used the Langmuir technique. Since the data of Refs. 1 and 3 do not drift, it may be assumed that the accommodation coefficient is unity or close to unity. The drift in the second set cannot be eliminated by assuming a non-unity accommodation coefficient, nor does there appear to be a constant pressure error. Most probably the drift is due to slight errors in temperature. For example, if the readings were 24° high at the low end and 10° low at the high end, the drift would be eliminated; errors of this magnitude are quite possible. The value adopted for $\Delta H_f^{298.15}$ is 203.4 ± 1.5 kcal/mol.

Heat Capacity and Entropy.

The electronic energy levels were taken from those listed by C. E. Moore, U. S. Natl. Bur. Std. Circular 467 (1958). Levels above 25000 cm⁻¹ were averaged.

Heat of Formation.

The heat of formation is obtained by adding the heat of ionization at 0°K to the ΔH_f^o W(g). The heat of ionization, 184.056 kcal (7.98 eV), is obtained from C. E. Moore, Natl. Bur. Std. Circular 467, Vol. III, Washington D. C. (1958).

Heat Capacity and Entropy.

The electronic energy levels are obtained from C. E. Moore, loc. cit. In the low lying configuration [Xe] $4f^{14}5d^5$ the F_2, G_2, F_2, H and S multiplets have not been observed. The total degeneracy of these levels (70) is split among three estimated levels of 20000, 21000, and 22000 cm^{-1} , obtained by analogy with Mo^+ . A realistic uncertainty in these levels would produce a maximum uncertainty of 0.03 gibbs/mol in the free energy function and 0.09 gibbs/mol in the entropy at 6000°K.

The enthalpy at 0°K is -1.487 kcal/mol.

S°_{298.15} = 9.314 ± 0.10 gibbs/mol

ΔH°_{298.15} = 0 kcal/mol

ΔH°_{298.15} = 0 kcal/mol

ΔH°_{298.15} = 0 kcal/mol

T_m = 1135 ± 5°K

Heat of Formation

Zero by definition.

Heat Capacity and Entropy

The low temperature heat capacities, 1.1 - 298.2°K, have been measured by Todd (1), Skinner (2), Eastermann (3), Wolcott (4), Burk (5), and Kneip (6). Values of Cp_{298.15} were reported as 6.19 and 6.01 gibbs/mol by Todd (1) and Skinner (2), respectively. The difference (beginning at 180°K) is probably caused by different amounts of impurities (e.g. O₂, H₂, N₂) in the samples. Neither sample was analyzed for hydrogen and oxygen content. Small amounts of either of these impurities would cause important changes in Cp. Remeasurement of Cp using a high purity sample is desirable to resolve the difference. Tentatively, we adopt smooth Cp values which are intermediate between those of Todd and Skinner in the temperature range 200 - 298°K. The curve at lower temperatures is based on references 1, 2, 4, 5 and 6. S°_{298.15} is derived from the adopted Cp based on S°₁₁₆ = 0.0008 eu.

Enthalpies have been measured using drop calorimetry by Jaeger (7), Coughlin (8), Skinner (9), Redmond (10), Adenstedt (11) and Douglas (13). Cp above 298°K has been measured by Scott (12) and Vollmer (15) using adiabatic calorimetry and by Klein (14) using pulse heating. The data lead to differences in Cp which are even greater than those noted at 298°K. Observed Cp's are lower than the adopted curve by roughly 3 to 6 per cent, but the observed enthalpies are generally higher by 0 to 10 per cent. Impurities are partly to blame but there also may be a systematic difference between the methods. The purest and best-characterized samples are those of Douglas (13) and Vollmer (15). Even the high-purity sample of Douglas gives H values which are abnormally high at 573°K, suggesting the presence of thermal effects of solid solution and precipitation due to a small amount of hydrogen in the sample (12).

The adopted Cp is based mainly on Douglas (13), but references (7, 8, 9, 10, 11) were also given some weight. Deviations of (13) from the adopted values range from +3.3 per cent at 573°K to +0.3 at 1123°K. Other deviations (each in order of increasing T) are 3 to 0 per cent (7), 1.3 to -1.7 per cent (8), -4 to -6 per cent (9), -4 to -6 per cent (10), 5.4 to 1.7 per cent (11) and -1 to 9.5 per cent (14) in terms of enthalpy. Cp is extrapolated linearly above 1133°K.

Transition Data

See Zr(β) table for details.

Heat of Sublimation

ΔH°_{298.15} is calculated as the difference between ΔH°_{298.15} for Zr(g) and Zr(α).

$$S_{298.15}^{\circ} = 11.152 \text{ gibbs/mol}$$

$$\Delta H_{298.15}^{\circ} = 1.706 \text{ kcal/mol}$$

$$T_c = 1135 \pm 10^{\circ}\text{K}$$

$$\Delta H_c^{\circ} = 0.96 \text{ kcal/mol}$$

$$\Delta H_m^{\circ} = 5.0 \pm 0.3 \text{ kcal/mol}$$

Heat of Formation

The heat of formation is obtained from $\Delta H_{298}^{\circ}(\alpha)$ by adding ΔH° and the difference between H_{Tc}° - H_{298}° for Zr(α) and Zr(β).

Heat Capacity and Entropy

The enthalpies and Cp of Zr(β), at temperatures 1135 - 2118.2 °K, have been measured by many investigators (see Zr(α) table for details). The selected Cp values are based on the data reported by Douglas (2) and Skinner (2). Deviations from the adopted enthalpies are -1.4 to 0.8 per cent (1), -0.4 to 0.3 (2), and 0.2 to 3.0 per cent (3). Deviations of the measured Cp from the adopted values are -5 to -3 per cent (14) and about -6 per cent (10). The heat capacities below 1143.2 and above 1798°K are estimated by linear extrapolation.

The entropy is obtained in a manner analogous to that of the heat of formation.

Transition Data

Zirconium has two crystal forms, i.e., the hexagonal-close-packed α -form and the cubic-body-centered β -form (3, 4, 5). The value and range of Tt for $\alpha + \beta$ depends strongly on the kind and amount of impurities (5, 13). For example, nitrogen and oxygen increase Tt while hydrogen decreases it. The adopted value is Tt = 1135 \pm 10°K, although recent measurements using purer samples indicate a somewhat higher value. These are summarized below along with the data for ΔH_c° . The value $\Delta H_c^{\circ} = 0.96 \text{ kcal/mol}$ is derived from the adopted enthalpy and Cp data on Zr(α) and Zr(β).

ZIRCONIUM (Zr)

(LIQUID)

GFW = 91.22

S°_{298.15} = [13.289] gibbs/mol

ΔH_f°_{298.15} = [6.351] kcal/mol

T_m = 2125 ± 5 °K

ΔH_m° = 5.0 ± 0.4 kcal/mol

T_b = [4776.9] °K

ΔH_v° = 141.13 kcal/mol

Heat of Formation

The heat of formation is obtained from ΔH_f°₂₉₈ (β) by adding ΔH_m° and the difference between H°₂₁₂₅ - H°₂₉₈ for Zr(β) and Zr(L).

Heat Capacity and Entropy

A glass transition temperature at 1400°K is assumed. The heat capacities below 1400°K are taken from those for Zr(β). The Cp value above 1400°K is estimated by comparison with that of Zr(β) at T_m and assumed to be constant in the temperature range 1400 - 5500°K. The entropy is obtained in a manner analogous to that of the heat of formation.

Melting Data

The melting point of Zr(β) has been determined by many investigators. The results reported show wide discrepancies, probably caused by the differences in purity of the samples used for determination. The T_m value adopted is obtained from Oriani and Jones. The other values of T_m reported are presented in the table below.

The adopted heat of melting was determined calorimetrically by V. P. Elyutin, M. A. Maurakh and G. M. Sverdlov, Izv. Vysshikh Uchebn. Zavedenii, Tsvetn. Met. 10, No. 2, 87 (1967). Zirconium samples from two different sources were melted in an Arc-crucible furnace. The crucible contained an insert of graphite which had a thick lining (presumably of zirconium carbide) in order to minimize carbonization of Zr(L). The molten Zr was poured through an opening in the bottom of the crucible into a calorimeter containing molten Mg as the calorimetric fluid. The method of calculating the value of ΔH_m° was described in detail by V. P. Elyutin, M. A. Maurakh, V. Y. Mishuk, and G. M. Sverdlov, Izv. Vysshikh Uchebn. Zavedenii, Tsvetn. Met. 10, 60 (1967). The authors estimated the uncertainty as about 7 percent in ΔH_m°.

Vaporization Data

T_b is the temperature at which the Gibbs energy change (ΔGr°) for the reaction Zr(L) = Zr(g) approaches zero. The difference between ΔH_f°(Zr, g) and ΔH_f°(Zr, l) at T_b is ΔH_v°.

Heat of Formation

Vapor pressures of Zr(β) and Zr(δ) were measured, using the Langmuir free-vaporization method, by Skinner (1) and Koch (3), respectively. Based on the reported results, the corresponding enthalpies of sublimation and vaporization are evaluated by the second and third law methods. See the table below for details. The values of evaporation rate and vapor pressure given by Koch in Table 2 on page 9 are too big by a factor of 10 due to typographical errors. The samples employed by Koch were prepared from iodide-process zirconium of 99.9 percent purity by tungsten-electrode melting in an inert atmosphere. The measured weight losses were in general more than one hundred times greater than those reported by Skinner. The value of ΔH°_{298} (Zr, g) adopted is 140.3 \pm 3.5 kcal/mol, which is derived using the data of Koch.

Truelsen (2) used a mass spectrometer with a high temperature Knudsen effusion source to obtain the vapor pressure for Zr(β) and Zr(δ). Based on the reported vapor pressures the values of heat of sublimation of Zr(β) are evaluated by the second and third law methods. The results are presented in the table below. Because of the uncertainties in obtaining absolute pressures from ion intensities, these results are not adopted.

Zwikker (4) determined the vapor pressures of Zr(β) by the Langmuir method. However, the zirconium sample was reported to be covered by an oxide layer during the measurement. Therefore, the pressures obtained are probably not the vapor pressures of pure zirconium and are not used for evaluation.

Investigator	Temperature, °K	No. of Points	ΔH°_{298} , kcal/mol	ΔH°_{298} , kcal/mol
1. Skinner (1951)	1951 - 2047	12	138.642.1	145.9
2. Truelsen (1965)	1968 - 2274	22	141.341.5	142.1
3. Koch (1968)	2229 - 2795	16	142.724.3	141.9

*Calculation based on the third law ΔH°_{298} , $\Delta H^{\circ}_{298}(\beta) = 1.706$ and $\Delta H^{\circ}_{298}(\delta) = 6.351$ kcal/mol.

Heat Capacity and Entropy

The electronic levels and quantum weights are obtained from Moore (5). Above the level $E_i = 15932.10$ cm⁻¹, the values of E_i and g_i listed in the above table are average values calculated from those given by Moore. The entropy contributed by the unobserved electronic is estimated to be less than 0.1 eu at 6000°K.

Heat of Formation

The heat of formation is calculated from the reaction $\text{Zr(g)} - e^-(\text{g}) = \text{Zr}^+(\text{g})$ with the JANAF auxiliary value for Zr(g) ; and an ionization potential = 6.84 eV or 157.737 kcal/mol, obtained from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. II, 1952 and Vol. III, 1958.

Heat Capacity and Entropy

The electronic levels and quantum weights are taken from C. E. Moore, "Atomic Energy Levels," Natl. Bur. Std. Circ. 467, Vol. II, 1952 and Vol. III, 1958. The electronic levels above 2500 cm^{-1} are averaged. The $H^\circ - H_{298}^\circ$ value at 0°K is -1.786 kcal/mol.

Electron Gas (e⁻)

(Reference State) At. Wt. = 0.00054876

ELECTRON GAS (e⁻)

(REFERENCE STATE)

AT. WT. = 0.00054876

0 to 6000°K. IDEAL GAS

 $S_{298.15}^{\circ} = 4.988 \text{ cal. deg.}^{-1} \text{ mole}^{-1}$ $\Delta H_f^{\circ} 298.15 = 0$

Electronic Levels and Multiplicities

$$\frac{\epsilon_i \text{ cm.}^{-1}}{0} \cdot \frac{g_i}{2}$$

Heat of Formation.

Zero by definition.

Heat Capacity and Entropy.

Calculated by assuming to be an ideal monatomic gas of mass 0.00054876 with two equivalent spin states. The enthalpy between 298 and 0°K. is 1.461 kcal. mole⁻¹ as for all unexcited monatomic gases.

Publications in the National Standard Reference Data Series

National Bureau of Standards

You may use this listing as your order form by checking the proper box of the publication(s) you desire or by providing the full identification of the publication you wish to purchase. The full letter symbols with each publication number and full title of the publication and author must be given in your order, e.g. NSRDS-NBS-17, Tables of Molecular Vibrational Frequencies, Part 3, by T. Shimanouchi.

Pay for publications by check, money order, or Superintendent of Documents coupons or deposit account. Make checks and money orders payable to Superintendent of Documents. Foreign remittances should be made either

by international money order or draft on an American bank. Postage stamps are not acceptable.

No charge is made for postage to destinations in the United States and possessions, Canada, Mexico, and certain Central and South American countries. To other countries, payments for documents must cover postage. Therefore, one-fourth of the price of the publication should be added for postage.

Send your order together with remittance to Superintendent of Documents, Government Printing Office, Washington, D.C. 20402.

- ☐ NSRDS-NBS 1, **National Standard Reference Data System—Plan of Operation**, by E. L. Brady and M. B. Wallenstein, 1964 (15 cents), SD Catalog No. C13.48:1.
- ☐ NSRDS-NBS 2, **Thermal Properties of Aqueous Uni-univalent Electrolytes**, by V. B. Parker, 1965 (45 cents), SD Catalog No. C13.48:2.
- ☐ NSRDS-NBS 3, Sec. 1, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si II, Si III, Si IV**, by C. E. Moore, 1965 (35 cents), SD Catalog No. C13.48:3/Sec.1.
- ☐ NSRDS-NBS 3, Sec. 2, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, Si I**, by C. E. Moore, 1967 (20 cents), SD Catalog No. C13.48:3/Sec.2.
- ☐ NSRDS-NBS 3, Sec. 3, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, C I, C II, C III, C IV, C V, C VI**, by C. E. Moore, 1970 (\$1), SD Catalog No. C13.48:3/Sec.3.
- ☐ NSRDS-NBS 3, Sec. 4, **Selected Tables of Atomic Spectra, Atomic Energy Levels and Multiplet Tables, N IV, N VI, N VII**, by C. E. Moore, (in press).
- ☐ NSRDS-NBS 4, **Atomic Transition Probabilities, Volume I, Hydrogen Through Neon**, by W. L. Wiese, M. W. Smith and B. M. Glennon, 1966 (\$2.50), SD Catalog No. C13.48:4/Vol.1.
- ☐ NSRDS-NBS 5, **The Band Spectrum of Carbon Monoxide**, by P. H. Krupenie, 1966 (70 cents), SD Catalog No. C13.48:5.
- ☐ NSRDS-NBS 6, **Tables of Molecular Vibrational Frequencies, Part 1**, by T. Shimanouchi, 1967 (40 cents), SD Catalog No. C13.48:6/Pt.1.
- ☐ NSRDS-NBS 7, **High Temperature Properties and Decomposition of Inorganic Salts, Part 1, Sulfates**, by K. H. Stern and E. L. Weise, 1966 (35 cents), SD Catalog No. C13.48:7/Pt.1.
- ☐ NSRDS-NBS 8, **Thermal Conductivity of Selected Materials**, by R. W. Powell, C. Y. Ho, and P. E. Liley, 1966 (\$1), PB189698.
- ☐ NSRDS-NBS 9, **Tables of Bimolecular Gas Reactions**, by A. F. Trotman-Dickenson and G. S. Milne, 1967 (\$2), SD Catalog No. C13.48:9.
- ☐ NSRDS-NBS 10, **Selected Values of Electric Dipole Moments for Molecules in the Gas Phase**, by R. D. Nelson, Jr., D. R. Lide, Jr., and A. A. Maryott, 1967 (40 cents), SD Catalog No. C13.48:10.
- ☐ NSRDS-NBS 11, **Tables of Molecular Vibrational Frequencies, Part 2**, by T. Shimanouchi, 1967 (30 cents), SD Catalog No. C13.48:11/Part 2.
- ☐ NSRDS-NBS 12, **Tables for the Rigid Asymmetric Rotor: Transformation Coefficients from Symmetric to Asymmetric Bases and Expectation Values of P_z^2 , P_y^2 , and P_x^2** , by R. H. Schwendeman, 1968 (60 cents), SD Catalog No. 13.48:12.
- ☐ NSRDS-NBS 13, **Hydrogenation of Ethylene on Metallic Catalysts**, by J. Horiuti and K. Miyahara, 1968 (\$1), SD Catalog No. C13.48:13.
- ☐ NSRDS-NBS 14, **X-Ray Wavelengths and X-Ray Atomic Energy Levels**, by J. A. Bearden, 1967 (40 cents), SD Catalog No. C13.48:14.
- ☐ NSRDS-NBS 15, **Molten Salts, Vol. 1, Electrical Conductance, Density, and Viscosity Data**, by G. J. Janz, F. W. Dampier, G. R. Lakshminarayanan, P. K. Lorenz, and R. P. T. Tomkins, 1968 (\$3), SD Catalog No. C13.48:15/Vol.1.
- ☐ NSRDS-NBS 16, **Thermal Conductivity of Selected Materials, Part 2**, by C. Y. Ho, R. W. Powell, and P. E. Liley, 1968 (\$2), SD Catalog No. C13.48:16/Pt.2.
- ☐ NSRDS-NBS 17, **Tables of Molecular Vibrational Frequencies, Part 3**, by T. Shimanouchi, 1968 (30 cents), SD Catalog No. C13.48:17/Pt.3.
- ☐ NSRDS-NBS 18, **Critical Analysis of the Heat-Capacity Data of the Literature and Evaluation of Thermodynamic Properties of Copper, Silver, and Gold From 0 to 300°K**, by G. T. Furukawa, W. G. Saba, and M. L. Reilly, 1968 (40 cents), SD Catalog No. C13.48:18.
- ☐ NSRDS-NBS 19, **Thermodynamic Properties of Ammonia as an Ideal Gas**, by L. Haar, 1968 (20 cents), SD Catalog No. C13.48:19.
- ☐ NSRDS-NBS 20, **Gas Phase Reaction Kinetics of Neutral Oxygen Species**, by H. S. Johnston, 1968 (45 cents), SD Catalog No. C13.48:20.
- ☐ NSRDS-NBS 21, **Kinetic Data on Gas Phase Unimolecular Reactions**, by S. W. Benson and H. E. O'Neal, 1970 (\$7), SD Catalog No. C13.48:21.
- ☐ NSRDS-NBS 22, **Atomic Transition Probabilities, Vol II, Sodium Through Calcium, A Critical Data Compilation**, by W. L. Wiese, M. W. Smith, and B. M. Miles, 1969 (\$4.50), SD Catalog No. C13.48:22/Vol.II.
- ☐ NSRDS-NBS 23, **Partial Grottrian Diagrams of Astrophysical Interest**, by C. E. Moore and P. W. Merrill, 1968 (55 cents), SD Catalog No. C13.48:23.
- ☐ NSRDS-NBS 24, **Theoretical Mean Activity Coefficients of Strong Electrolytes in Aqueous Solutions from 0 to 100° C**, by Walter J. Hamer, 1968 (\$4.25), SD Catalog No. C13.48:24.
- ☐ NSRDS-NBS 25, **Electron Impact Excitation of Atoms**, by B. L. Moiseiwitsch and S. J. Smith, 1968 (\$2), SD Catalog No. C13.48:25.
- ☐ NSRDS-NBS 26, **Ionization Potentials, Appearance Potentials, and Heats of Formation of Gaseous Positive Ions**, by J. L. Franklin, J. G. Dillard, H. M. Rosenstock, J. T. Herron, K. Draxl, and F. H. Field, 1969 (\$4), SD Catalog No. C13.48:26.
- ☐ NSRDS-NBS 27, **Thermodynamic Properties of Argon from the Triple Point to 300 K at Pressures to 1000 Atmospheres**, by A. L. Gosman, R. D. McCarty, and J. G. Hust, 1969 (\$1.25), SD Catalog No. C13.48:27.
- ☐ NSRDS-NBS 28, **Molten Salts, Vol. 2, Section 1, Electrochemistry of Molten Salts: Gibbs Free Energies and Excess Free Energies From Equilibrium-Type Cells**, by G. J. Janz and C. G. M. Dijkhuis. **Section 2, Surface Tension Data**, by G. J. Janz, G. R. Lakshminarayanan, R. P. T. Tomkins, and J. Wong, 1969 (\$2.75), SD Catalog No. C13.48:28/Vol.2.
- ☐ NSRDS-NBS 29, **Photon Cross Sections, Attenuation Coefficients and Energy Absorption Coefficients From 10 keV to 100 GeV**, by J. H. Hubbell, 1969 (75 cents), SD Catalog No. C13.48:29.
- ☐ NSRDS-NBS 30, **High Temperature Properties and Decomposition of Inorganic Salts, Part 2, Carbonates**, by K. H. Stern and E. L. Weise, 1969 (45 cents), SD Catalog No. C13.48:30.
- ☐ NSRDS-NBS 31, **Bond Dissociation Energies in Simple Molecules**, by B. deB. Darwent, 1970 (55 cents), SD Catalog No. C13.48:31.
- ☐ NSRDS-NBS 32, **Phase Behavior in Binary and Multicomponent Systems at Elevated Pressures: *n*-Pentane and Methane-*n*-Pentane**, by V. M. Berry and B. H. Sage, 1970 (70 cents), SD Catalog No. C13.48:32.
- ☐ NSRDS-NBS 33, **Electrolytic Conductance and the Conductances of the Halogen Acids in Water**, by W. J. Hamer and H. J. DeWane, 1970 (50 cents), SD Catalog No. C13.48:33.
- ☐ NSRDS-NBS 34, **Ionization Potentials and Ionization Limits Derived from the Analyses of Optical Spectra**, by C. E. Moore, 1970 (75 cents), SD Catalog No. C13.48:34.

**Announcement of New Publications in
National Standard Reference Data Series**

Superintendent of Documents,
Government Printing Office,
Washington, D.C. 20402

Dear Sir:

Please add my name to the announcement list of new publications to be issued in the series: National Standard Reference Data Series—National Bureau of Standards.

Name_____

Company_____

Address_____

City_____ State_____ Zip Code_____

(Notification key N-337)

U.S. DEPT. OF COMM. BIBLIOGRAPHIC DATA SHEET	1. PUBLICATION OR REPORT NO. NSRDS-NBS 37	2. Gov't Accession No.	3. Recipient's Accession No.
4. TITLE AND SUBTITLE JANAF Thermochemical Tables, Second Edition		5. Publication Date	
		6. Performing Organization Code	
7. AUTHOR(S) D. R. Stull, H. Prophet, et al.		8. Performing Organization	
9. PERFORMING ORGANIZATION NAME AND ADDRESS NATIONAL BUREAU OF STANDARDS DEPARTMENT OF COMMERCE WASHINGTON, D.C. 20234		10. Project/Task/Work Unit No.	
		11. Contract/Grant No. F04611-67-C-0009 F04611-70-0028	
12. Sponsoring Organization Name and Address The Thermal Research Laboratory Dow Chemical Company Midland, Michigan		13. Type of Report & Period Covered NA	
		14. Sponsoring Agency Code	
15. SUPPLEMENTARY NOTES Superseding PB168-370 and Addenda 1, 2, and 3			
16. ABSTRACT (A 200-word or less factual summary of most significant information. If document includes a significant bibliography or literature survey, mention it here.) This monograph is the second edition of the JANAF Thermochemical Tables. It contains thermodynamic properties for some 1099 chemical species. The following properties are tabulated as functions of temperatures: C_p° , S° , $(F^\circ - H_{298}^\circ)/T$, $H^\circ - H_{298}^\circ$, ΔH_f° and Log Kp.			
17. KEY WORDS (Alphabetical order, separated by semicolons) Evaluated Data; Thermal Functions; Thermodynamic Properties of Materials; Thermodynamics.			
18. AVAILABILITY STATEMENT <input checked="" type="checkbox"/> UNLIMITED. <input type="checkbox"/> FOR OFFICIAL DISTRIBUTION. DO NOT RELEASE TO NTIS.		19. SECURITY CLASS (THIS REPORT) UNCLASSIFIED	21. NO. OF PAGES 1141
		20. SECURITY CLASS (THIS PAGE) UNCLASSIFIED	22. Price \$9.75
